I. INTRODUCTION

A. OVERVIEW

This thesis develops a Lanchester-type force-on-force combat model simulating small-unit amphibious operations. The model commences with a ship-to-shore assault of aggressor forces (e.g., a U.S. Marine Infantry Battalion), mounted onboard Landing Vehicle Assault craft (LVA) moving against a defensive force ashore located in fixed positions along the coast the aggressor force is attempting to occupy. Once the ship-to-shore phase of combat is completed, the model continues to simulate land combat further inland between the assaulting aggressor forces and other defensive forces occupying key terrain.

The main thrust of the thesis is to alleviate some of the problems associated with the inherent abstractness of Lanchester-type combat models (see [Ref. 1]), and specifically to integrate and enhance work done in previous models, to develop "user-friendly" enhancements, and more thorough documentation of algorithms to provide a model which would be more easily understood and utilized by students of combat modeling.

B. BACKGROUND AND GENERAL MODEL

1. Overview

The small-unit amphibious operation combat model presented in this thesis is the result of the integration and enhancement of two independent combat models. The first model is a ship-to-shore combat model which models a ship-to-shore assault conducted by landing vehicle assault craft against fixed enemy positions ashore. The second model

is a land combat model which models a land assault conducted by LVA forces on a beach, against fixed enemy positions further inland.

2. Original Ship-to-Shore Combat Model

The ship-to-shore combat model used as a basis for this thesis was presented in a thesis by David L. Chadwick [Ref. 2]. It modeled the amphibious assault of five waves of LVA against a defensive force composed of tanks and antitank guided missiles (ATGM) in fixed positions ashore. Attrition was modeled using Lanchester area-fire and aimed-fire equations. The purpose of developing such a model was to determine the optimal design characteristics of LVA in an amphibious assault for a given combat scenario. The optimal design of an LVA was considered to be that design which produced the lowest level of LVA attrition for the given combat scenario.

3. Original Land Combat Model

The land combat model used as a basis for this thesis was developed in Joseph Smoler's thesis [Ref. 3]. It modeled land combat conducted by three aggressor force units utilizing tanks assaulting three defensive force units armed with Tube-Launched, Optical-Guided, Wire-Controlled missiles (TOW's) in fixed positions. The location of the land combat was the Fulda Gap region in West Germany. Attrition was modeled using Lanchester aimed-fire equations. The purpose of Smoler's thesis was to develop a basic small-unit land combat model for determining optimal defensive unit locations for a given combat scenario. The optimal locations of the defensive units were considered to be those locations which provided the lowest level of attrition of the defensive units for the given combat scenario.

4. The Enhanced Land Combat Model

An enhanced version of Smoler's land combat model was developed by Glenn Mills in his thesis [Ref. 4]. The enhancements developed by Mills added flexibility to Smoler's land combat model by providing user selected options which could be employed depending upon the abilities and desires of the model's user. The enhancements included the option of altering the aggressor force's attack routes enabling the user to study not only the optimal defensive unit locations, but the optimal aggressor force attack routes for the given defensive unit locations as well.

A second enhancement was the option of selecting a stochastic attrition-rate coefficient. This introduced the element of randomness into the model's attrition algorithm providing a more realistic approach to modeling a unit's fighting effectiveness.

The third enhancement is the option of providing alternate defensive positions so that the defensive units could move to more defensible terrain once their original positions had become untenable.

5. The Original Small-Unit Amphibious Warfare Model

The original small-unit amphibious warfare model used as a basis for this thesis was developed by Soon Dae Park in his thesis [Ref. 5]. Park's model attempted to conceptualize the flow of events of an amphibious assault by first running the ship-to-shore model, followed immediately by running the land combat model. The analysis of this model as a class project served as the catalyst for the development of the small-unit amphibious operation combat model presented in this thesis.

6. The Analysis of Park's Model

The class project conducted by Clay Grubb, Robert Larson, and this author had as its purpose the analysis of Soon Dae Park's small-unit amphibious operation combat model. The results of the analysis revealed the value of Park's thesis in providing a general scheme of events for the modeling of small-unit amphibious operations. The results also identified some enhancements that could be applied to his conceptualized model that would integrate the ship-to-shore and land combat models into a singular small-unit amphibious operation combat model. The development and application of these enhancements to Park's model served as the foundation for this thesis, and the development of the model presented.

C. MAJOR GOAL AND OBJECTIVES OF THE THESIS

1. Major Goal of the Thesis

The overall goal of the thesis is the development of a small-unit amphibious operation combat model. It will be based on the integration and enhancement of the two combat models discussed in the previous section of this chapter. There are three underlying objectives of the thesis which will guide the development of the model toward the accomplishment of this goal.

2. Objectives of the Thesis

a. Integration of Independent Combat Models

The first objective in the development of the model was to integrate two initially independent combat models into a singular continuous flow combat model. This was accomplished by first allowing force levels at the completion of the ship-to-shore phase of combat to be used as the initial force levels in the land phase of combat.

Secondly, it was recognized that four combat modelers contributed to the resulting model presented by Park in his thesis. As such, four individualized FORTRAN coding techniques were reformulated into one style to provide a more tractible small-unit amphibious operation combat model.

b. User-Friendly Input-Data and Output Structure

The second objective of the thesis was to provide a user-friendly combat model. It is a major contention of this thesis that combat modelers have not adhered closely to this principle when providing combat models for the United States military. Furthermore, it is believed that the lack of concern given to this approach of combat modeling is a major reason for the less than unanimous reception that combat models have received by the United States military as tools for training its commanders and staffs. Therefore, the model presented in this thesis was designed and documented with the user's capabilities and needs in mind as opposed to those of the programmer.

c. Student-Oriented Combat Model

The third objective of the thesis was to provide the student of combat modeling with a combat model which was easily understood and studied. As a result, the model presented in this thesis was designed with a low level of complexity to allow the student with little or no experience in combat modeling to understand more easily the combat modeling theory and its application.

II. MODEL ENHANCEMENTS

A. OVERVIEW

This thesis had as its goal the development of a small-unit amphibious operation combat model. Guided by the three objectives discussed in Chapter One, five modeling enhancements were applied to the two original combat models serving as the foundation for the resulting small-unit amphibious operation combat model presented in this thesis. The enhancements provide for the proper integration of the ship-to-shore and land combat models. In addition, they have contributed to the development of a more user-friendly combat model which can be used to assist combat modeling students in their understanding the theory of combat modeling and its application.

B. INTEGRATION OF SHIP-TO-SHORE AND LAND COMBAT MODELS

The intent of the model presented here is to view the amphibious assault as a continuous process made up of two phases of combat (ship-to-shore, and land combat) where the land combat phase is dependent upon the outcome of the ship-to-shore combat phase of the model.

Implementation of this enhancement called for the creation of a new variable, Total Landing Force Ashore (TLF), which would accumulate the surviving landing force of each assault wave as it reached the beach. This total landing force ashore would then be redistributed into three main assault units for the land combat phase of the model. The rationale for the redistribution of forces is based on realistic

military doctrine which is to maintain a well-balanced force when the strength and location of the enemy is unknown to the assaulting forces (as is assumed in the model).

Since the manner in which defender force levels are determined by the ship-to-shore and land combat models appears to be quite realistic, the defending force level as modeled by Soon Dae Park was used as input to the land combat phase. In particular, if the aggressor force had been successful in routing the defending forces situated on the beach, defending forces situated further inland naturally would be impelled to defend the remaining terrain still in their possession. It should be noted that the size of these defending forces further inland is an option of the user which in itself can be varied for analysis of variant battle scenarios.

C. AGGRESSOR FORCE ATTRITION--SHIP-TO-SHORE PHASE

Attrition in Lanchester-type combat modeling is based upon the expected percentage of the original force remaining at a given point in time. The expected percentage of forces remaining then can be restated in terms of a real number to represent the expected number of forces remaining. This method of computing reduced force levels is considered to be quite appropriate when modeling land combat, and was implemented by Chadwick in his ship-to-shore combat model to simulate LVA attrition. However, use of Lanchester equations to model such vehicular attrition of a vehicle at sea was determined to be inappropriate. Where it is a reasonable assumption that a disabled vehicle on land still can contribute something toward the final outcome of the battle if any of its weapons systems or onboard troops survive,

an LVA that is disabled at sea is of no use to the amphibious assault and subsequent land combat phase. The LVA will be recovered, and on-board troops brought to the landing site after the assault has taken place.

Chadwick was not concerned with this distinction due to his model's purpose of modeling LVA attrition in terms of ship-to-shore movement only. Therefore, he simply utilized Lanchester equations in modeling LVA attrition resulting in fractionalized losses of assaulting LVA's. However, if a ship-to-shore combat model is to be properly integrated with a land combat model, only whole numbers of LVA's ashore should be used as input. Hence, an enhancement was made to the model.

The approach was to find the integer value of the number of surviving LVA's in each assault wave, and then sum these values resulting in the total landing force ashore (TLF). The fractional portion remaining was considered to be those LVA's disabled at sea and unable to participate in the land combat phase of the operation.

D. STOCHASTIC ATTRITION-RATE COEFFICIENT MODIFICATION

Mill's land combat model allowed the user the option of selecting either deterministic or stochastic attrition-rate coefficients to be used in assessing the attrition of opposing forces. The justification for utilizing stochastic attrition-rate coefficients to model force-on-force attrition rates was based upon the assumption that the attrition-rate coefficient is a random quantity measuring a unit's fighting ability, and can be estimated before any given battle.

This can be illustrated by considering the expected value of a random variable. For example, assume a probability distribution is

selected for the random variable such that the expected value of the random variable is equal to the deterministic attrition-rate coefficient set for all units. When a random sample is taken from this distribution, the individual values assigned the random variable will serve as individual unit attrition-rate coefficients, where the sample mean will serve as the overall force attrition-rate coefficient. The result is that the overall force attrition-rate is equal to the sample mean, which is approximately equal to the population mean of the random variable. Recalling that this population was selected with a mean that equalled the deterministic attrition-rate coefficient, units now have their own individual attrition-rate coefficients, while the force attrition-rate coefficient has remained close to the intended value of the deterministic attrition-rate coefficient. This is more realistic than the deterministic option since each unit would be expected to have a different level of effectiveness, which necessarily would imply different attrition rates while maintaining one overall force level attrition rate.

The attrition-rate coefficient, A_{ij} , is used as the measure of the rate a firer in Unit i attrits a target in Unit j . This has been likened to the fighting effectiveness of a particular Unit i . Obviously, this is a variable quantity influenced by a myriad of factors to include esprit de corps, past history of success or failure, prior exposure to combat, weather, quality of leadership, etc. The intent of such a basic model as this is to attempt to capture the overall effect of these factors by developing a distribution of a unit's initial fighting capabilities (specifically, to develop a distribution of A_{ij} 's for the unit).

Mills proposed a distribution based upon a quadratic function which would produce a symmetric distribution with a mean value of approximately 0.55. This distribution restricted a unit's maximum effectiveness to only 80 percent of its maximum capable effectiveness level. It also implied that the average unit in combat will only perform at 55 percent of its maximum effectiveness level at any given time.

A more plausible way of assigning a distribution to the A_{ij} 's might be a truncated Normal Distribution limited to values between 0.00 and 1.00. However, this approach would leave little flexibility in terms of modeling variant scenarios since the opposing forces always would have attrition-rate coefficients associated with that particular distribution whenever the stochastic option was selected. This restriction is due to the programming constraints encountered in attempting to implement variant truncated Normal Distributions in the model. Therefore, a Beta Distribution was selected for use in the model.

The natural range of the Beta Distribution is from 0.00 to 1.00 thereby alleviating the burden of constructing a truncated distribution. Furthermore, its two scaling parameters, P and Q, can be selected readily and input by the user to construct virtually any variant of the Beta Distribution so desired. The specific values selected for P and Q would parameterize the distribution of the A_{ij} 's according to the user's particular combat scenario without the burden of reprogramming the distribution on each successive run of the model.

The density function for the Beta Distribution is as follows:

$$f(x) = x^{P-1}(1-x)^{Q-1} \quad \text{for } 0.0 \leq x \leq 1.0$$

$$\text{with } \mu_x = \frac{P}{P+Q}$$

Therefore, a $P=21$ and $Q=7$ would yield a distribution of A_{ij} 's with a mean of 0.75. This says that a unit with an A_{ij} of 0.75 is operating at 75 percent of its potential effectiveness. Whereas, a $P=7$ and $Q=21$ would yield a distribution of A_{ij} 's with a mean of 0.25, indicating that a unit is operating at 25 percent of its potential effectiveness.

To illustrate the flexibility of this approach in determining stochastic attrition-rate coefficients, Figure 2-1 is provided displaying the distribution of A_{ij} 's that would be obtained when the user alters the parameters of the Beta Distribution. The user now can model a strong elite force using, for example, parameter values $P=21$, $Q=7$, or model a weak and poorly lead force using parameter values $P=7$ and $Q=21$, depending upon the particular battle scenario the user is analyzing.

While the Beta Distribution used in this thesis is different than the Quadratic Distribution used by Glenn Mills, the implementation of this distribution for the attrition-rate coefficients is exactly the same as originally modeled. Since it was assumed earlier that the fighting effectiveness of each unit is a random quantity prior to a given battle, it is only necessary to obtain a realization of the random variable for each unit prior to the initialization of the battle. This realization, A_{ij}^0 , is determined by the user-supplied inputs P and Q , and subsequent calls to a Beta Distribution Random Deviate Generator [Ref. 6]. Therefore, an attrition-rate coefficient is computed for each unit using the following equation:

$$A_{ij} = \begin{cases} A_{ij}^0 \times (1 - r/r_e)^2 & \text{for } 0 \leq r \leq r_e \\ 0 & \text{for } r_e \leq r \end{cases}$$

BETA DENSITY

$$f(x) = x^{P-1} (1-x)^{Q-1}$$

Figure 2-1. Beta Density

Where: A_{ij}^0 = Realization of unit's fighting effectiveness
 r = Current range between firer and target
 r_e = Maximum effective range of a firer's weapon

This function was utilized because it is a function of both range and A_{ij}^0 thus creating a different attrition-rate curve for each unit, depending on that unit's effectiveness level prior to the battle. A graphic illustration of an attrition-rate coefficient curve for an A_{ij}^0 equal to a mean of 0.75 from the Beta Distribution where $P=21$ and $Q=7$, and the maximum effective range r_e , of 3000 meters would look like Figure 2-2.

Figure 2-2. Attrition-Rate Coefficient Curve for $A_{ij}^0 = 0.75$ and $r_e = 3000m$

To illustrate the effect that this stochastic attrition option has on the outcome of the model, two runs of the model were made using this option, while varying the Beta Distribution parameter values for both forces on each run. All other characteristics of both forces were left unaltered. In the first run, the aggressor forces were modeled to operate at 75 percent of their potential effectiveness, and the defending

forces were modeled to operate at 25 percent of their potential effectiveness. The battle outcome, as listed in Table 2-1, indicates that the aggressor forces won the battle. In the second run, the potential effectiveness of the opposing forces was reversed. The aggressor forces were now modeled to operate at 25 percent of their potential effectiveness, and the defending forces were modeled to operate at 75 percent of their potential effectiveness. The battle outcome, as listed in Table 2-1, indicates that the battle was terminated due to the opposing forces being too close. The aggressor forces were unable to overrun the defending forces, as was the case in the first run, which was due solely to the change in the potential fighting effectiveness of the opposing forces.

A change in the battle outcome was expected; however, to what degree that change would be was unknown. The fact that the defender forces were unable to win the battle on the second run, while having a much higher level of effectiveness, indicates that other characteristics of the opposing forces were also playing an important role in the battle (e.g., types of weapons employed, original force levels, speed of attack, etc.).

Through the use of the stochastic attrition option, the user now has the capability of studying one more facet of combat (i.e., potential fighting effectiveness), and can analyze to what degree different fighting effectiveness levels will have on final battle outcome.

E. USER-FRIENDLY I/O STRUCTURE

A significant and important part of writing a computer program for a combat model is to provide for the input and output of data to and from the program. It is my belief that one of the major factors

Table 2-1. Comparison of Runs while Varying the Stochastic Attrition-Rate Parameters

Run No.	AGGRESSOR FORCES					DEFENDER FORCES					Time (sec)	Battle Outcome
	Percent Effectiveness	Resulting Force Level			Percent Effectiveness	Resulting Force Level						
		Unit 1	Unit 2	Unit 3		Unit 1	Unit 2	Unit 3				
1	75	0.0	4.8	17.9	25		0.0	0.0	0.0	745	A WINS	
2	25	0.0	0.0	18.0	75		0.0	5.0	0.0	865	T00 CLOSE	

contributing to the lukewarm reception, in general, that combat models have received by the United States military is due, in part, to the poorly designed input-data and output structure of the combat models. The primary user of those models, the military commander, normally finds it difficult to decipher the myriad of input-data requirements, or the voluminous output from combat models that supposedly were designed for the commander's use. It is a contention of this thesis that if more attention was given to the development of user-friendly input-data/output requirements, that more interest would be generated toward the use of such models in training military commanders. Therefore, an enhancement was made to the input-data and output requirements of the model to demonstrate a method of alleviating this problem.

1. User-Friendly Input Structure

A readymade input data file was provided with the model to serve as a guide for entering all of the required data in the correct format required by the model (see Appendix C). Each variable requiring input for the model has been listed in the sample input file with sufficient space provided for ensuring that data is entered in the correct format. This file, therefore, provides the unfamiliar user of the model with the opportunity to utilize the model with only a limited knowledge of the model's algorithm and input requirements. This type of user-oriented input requirement will alleviate some of the apprehension that an unfamiliar user of the program might have, and might actually act as a catalyst in increasing the amount of use the model receives.

2. User-Friendly Output Structure

Indecipherable output, or too much output from a model, can be just as much of a deterrent to a model's use as complex input requirements can be. This point was brought out by Ye S. Venttsel in her discussion of good combat models:

It is advisable in such "training" modeling of combat actions that the commander receive information from the computer not in the form of mean characteristics averaged over a set of realizations, but rather in the form of only one specific realization, on the basis of which a decision is in fact made. [Ref. 7]

To paraphrase Venttsel, the combat model output must be clear, concise, and identifiable to the military commander. Furthermore, it must answer the questions that were originally asked by the user--specifically, who won and why?

The model output was therefore restructured to provide a concise listing of what input parameters were entered into the program for processing, and a concise and understandable output summary of what occurred throughout the battle (see Appendix F). Additionally, a new feature was introduced into the model which gives the user the option of viewing either a detailed time-step battle summary, or just a final battle summary of what occurred in the running of the model.

F. DOCUMENTATION AND PROGRAM FORMAT

Two of the objectives of the model presented in this thesis were first to serve as an example of the way in which combat models should be designed to be user-friendly to ensure their acceptance and use in training military commanders; and secondly, to serve as a model for combat-modeling students so that they might acquire a better understanding of how combat models ought to be programmed into a computer.

It already has been discussed how the user-friendly I/O structure assists the user of the model. However, proper structuring of programs for readability and good documentation is equally necessary to ensure readability and understanding by students and analysts.

The FORTRAN program presented in this thesis which integrated and enhanced the ship-to-shore and land combat models is an amalgamation of subroutines originally written by different people, with their own unique style of programming. The interweaving of these four styles of programming throughout the program seriously detracted from the smooth flow of program structure and readability desired when analyzing the computer program. Therefore, an enhancement was made to the model: the program was restructured so that it would follow one basic style of programming (see Appendix B). New labeling and structuring of formatted statements and nested FORTRAN functions were provided to make the computer program more readable. This restructuring should assist the student in understanding the program flow, and provide an incentive to those interested students to develop future enhancements to the model.

In addition to developing one style of programming, more detailed documentation of variable definitions and descriptions of program flow were added to the program. The purpose of this documentation was to have the program serve as a reference to itself in order that the reader would not be forced to refer to various manuals outside of the program each time an explanation of the functioning of a particular aspect of the program is desired.

III. CURRENT MODEL DESIGN

A. OVERVIEW

The small-unit amphibious operation combat model presented in this thesis consists of the integration and enhancement of a ship-to-shore combat submodel, and a land combat submodel. Both of the original submodels were similar in design, basing force attrition on Lanchester-type expected-value equations. As presented earlier, enhancements to both submodels reduced the differences in design of these submodels, molding them into what may be called a small-unit amphibious operation combat model. Figure 3-1 provides the scheme for the sequence and general flow of events in the overall model.

It should be noted that although the ship-to-shore and land combat models are quite similar, they still have their own unique characteristics in modeling certain events that take place throughout the battle. Therefore, in discussing the model as a whole, the two phases of the battle will be addressed separately, and those events which are of particular interest in each phase of combat will be elaborated on in order that the reader might acquire an overall appreciation of the contributions each submodel makes to the overall model.

B. SHIP-TO-SHORE PHASE

1. Overview

Since the objectives of the thesis are to provide a user-friendly tractible combat model, a number of broad assumptions have been made regarding the exact method of employment of the LVA in the ship-to-shore

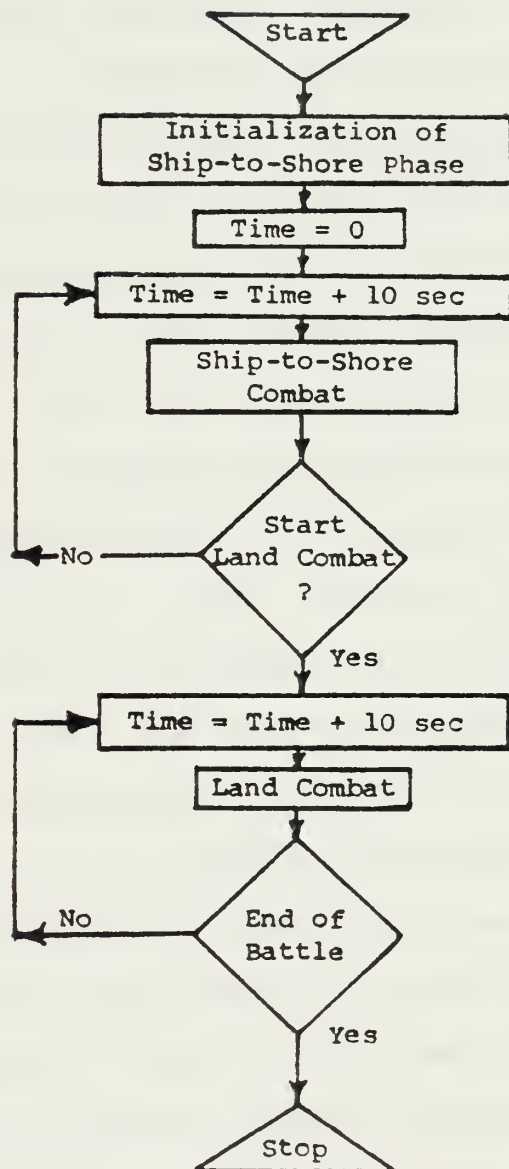

Figure 3-1. Generalized Flowchart for Small-Unit Amphibious Operation Combat Model

phase of the amphibious operation. First of all, it is envisioned that for command and control purposes, as well as for mine clearing operations, there will exist LVA approach lanes as depicted in Figure 3-2, along which columns of LVA will transit a 25-mile distance to shore from the Amphibious Task Force (ATF). The 25-mile distance is based upon recent requirements studies indicating that in future amphibious operations, due to the increased lethality of anti-ship missiles and long range artillery, it will be necessary to increase the Amphibious Task Force standoff distance to approximately 25 miles from shore to reduce the vulnerability of the amphibious shipping against this anticipated threat [Ref. 8]. Secondly, it is assumed that a maneuver area will exist within which the columns of waves of LVA will form into a conventional landing formation composed of waves of landing craft as prescribed by current doctrine.

The two previous assumptions set the stage for the primary assumption used in computing LVA force level attrition: that is, direct fire weapons will be assumed to be the primary anti-LVA threat--specifically, modified versions of current tank and antitank guided missiles (ATGM) assets. Although in reality some attrition of LVA can be expected in the maneuver area, it will be assumed that the critical exposure period will be that portion of time in the ship-to-shore movement that the first assault wave comes within 5,000 meters of the shore defenses until, up to, and including the arrival of the last assault wave ashore. Figure 3-3 is a flowchart depicting the general sequence of events of the ship-to-shore phase model.

2. LVA Movement Conceptualization

Two tactical decision variables were utilized for modeling LVA ship-to-shore movement:

Figure 3-2. LVA Approach Conceptualization

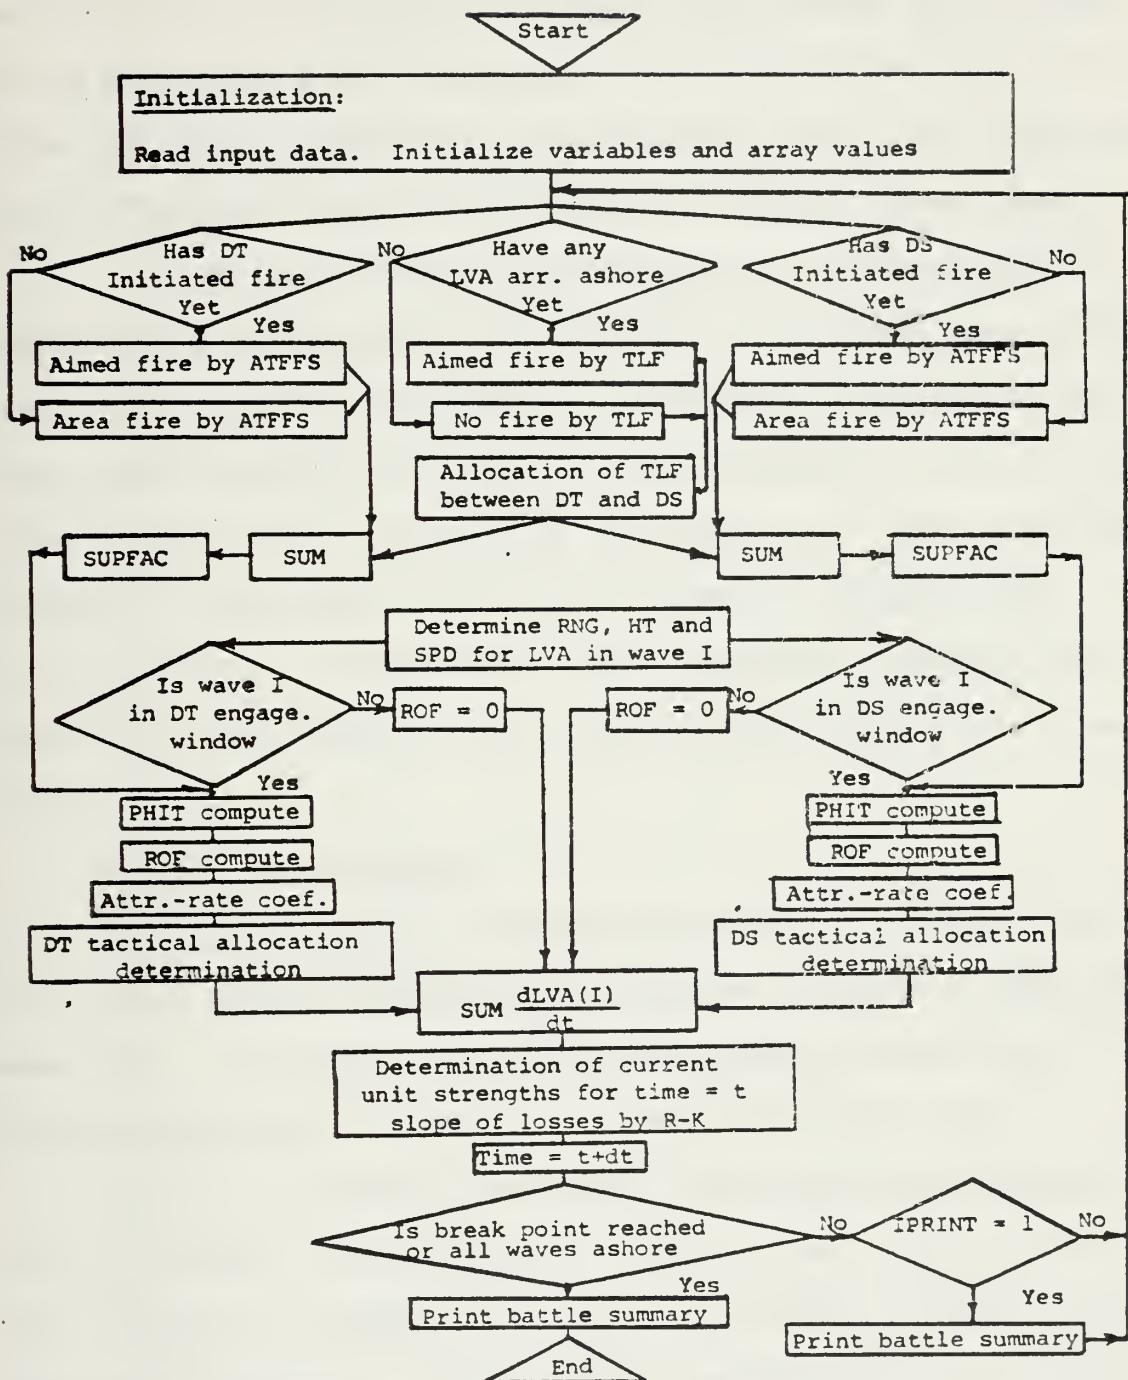

Figure 3-3. Generalized Flowchart for Ship-To-Shore Phase

--TBW is the decision variable for the time between successive waves. As TBW is shortened, coordination problems will arise resulting in confusion on the beach due to insufficient time provided for an assault wave to move inland prior to the next wave's arrival. The level of confusion generated by a short TBW must be balanced against the cost of not having sufficiently rapid initial buildup of offensive forces ashore.

--RD is the distance from the shoreline that each wave will commence the transition from planning model to displacement mode. This process will be termed a sequential wave transition since each of the assault waves sequentially performs the mode transition. This is illustrated in Figure 3-4. The reason for this transition is due to engineering stability requirements that this displacement configuration be achieved prior to crossing the surf line. The obvious effect of this transition is that exposure time to close-in direct-aimed fire will be created.

3. Overall Force Structure

The model aggregates the combat organizations involved in the ship-to-shore phase of the amphibious operation into several homogeneous combat units. Each unit is characterized by certain offensive and defensive capabilities in comparison to each of the other units.

Table 3-1 illustrates the combat organizations which have been explicitly modeled. The force level of each unit was represented by state variables as indicated. The initial force level for each unit is input-data to the model. This, therefore, permits the user to investigate alternative wave composition options as well as various defensive scenarios without having to make modifications to the model algorithm.

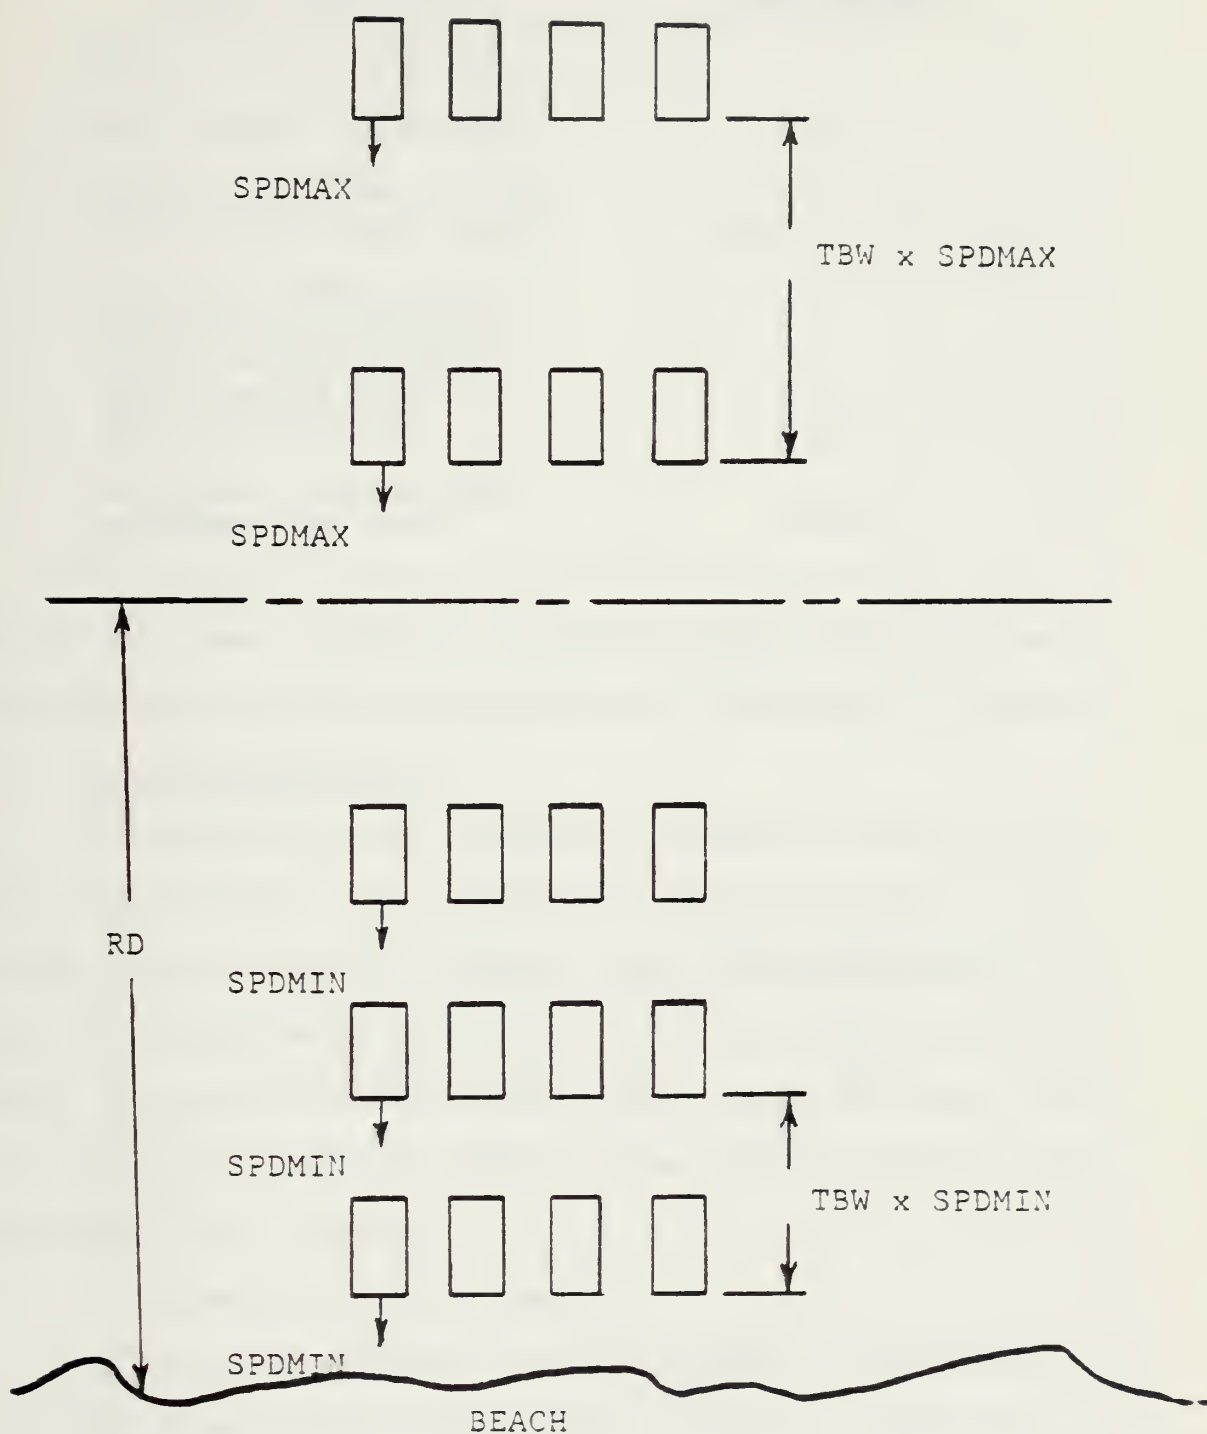

Figure 3-4. Tactical Employment Parameters-- Sequential Wave Transition

Table 3-1. State Variables Representing Combat Organizations

Combat Organization	State Variable
Shore Defenses - Tank Assets	DT
Shore Defenses - ATGM Assets	DS
Incoming assault Waves of LVA representing waves 1 thru 5	WV(I) I=1 thru 5
A cumulative combat force comprised of those Marine ground units which have arrived on the beach and debarked their LVA	TLF
Fire support assets of the amphibious task force	ATFFS

The tactical combat interactions that exist between these nine combat units within the overall force structure are illustrated in Figure 3-5.

4. Shore-Defense Scenario

The defensive scenario utilized in the model includes a force comprised of both tank (DT) and antitank guided missiles (DS). Tank and ATGM units are emplaced 75 meters inland of the waterline at an elevation of approximately 5-10 meters. The model does not explicitly maneuver or emplace individual tanks or ATGM systems within each unit, but aggregates the cumulative effects of the individual vehicles and weapons within each category.

a. Defensive Unit Force Levels

The state variables DT and DS represent the total unit "strengths" in each of the defensive unit categories. Specifically, a DT=3 indicates that within the shore defenses there exists a unit of tanks having a total combat effectiveness equivalent to three continuously

firing independent weapon systems. A similar interpretation is applicable to the state variable DS.

b. Defensive Fire Allocation

The two categories of direct-fire weapons are assumed to engage targets (incoming LVA) according to a predetermined tactical scheme. The defensive "plan" was parameterized as follows:

(1) Window of Engagement. Each weapon category was assigned an engagement window as illustrated in Figure 3-6. Only those LVA located within the range window could be fired upon by the shore defensive forces. The windows are designated by the following input parameters:

	<u>TANK</u>	<u>ATGM</u>
Maximum Engagement Range	TENCMX	SENGMX
Minimum Engagement Range	TENGMN	SENGMN

(2) Engagement Rules. Additional defensive tactical criteria are implemented into the model logic according to the following rules of engagement:

--A defensive weapon may only engage the two closest incoming waves if more than two waves of LVA are at any time located within the weapon's engagement window.

--If only one wave of LVA is present in a weapon's engagement window, defensive fires of that particular weapon type will be distributed uniformly against the surviving LVA in that wave.

--If two waves of LVA are both contained within the engagement window, defensive fires of that particular weapon type will be distributed according to a tactical allocation submodel. A weighting factor, (DEFWT), input by the user is utilized in establishing the proportion of the total weapon strength to be allocated against the

Figure 3-6. Engagement Window Parameters

surviving LVA's in each of the two waves. Specifically, if $DEFWT(1) = 2$, and $DEFWT(2) = 1$, then each surviving LVA in the closer of the two incoming waves would be allocated twice as much fire as surviving LVA in the seaward wave. For example, if waves three and four were both located within the ATGM engagement window, then the proportion of DS's fire allocated to surviving LVA in wave three would be:

$$\frac{DEFWT(1) \times WV(3)}{DEFWT(1) \times WV(3) + DEFWT(2) \times WV(4)} \times DS$$

where: $WV(3)$ is the state variable for the current number of survivors in wave 3

c. Attrition-Rate Coefficient Computation

The classical Lanchester hypothesis for aimed-fire attrition is that the casualty rate of a unit is proportional to the size of the opposing force. If a Unit "A" is being engaged by a Unit "D", this action may be expressed by the differential equation:

$$\frac{dA}{dt} = -\text{Beta}_{DA} \times D$$

where: Beta_{DA} is called the Lanchester attrition-rate coefficient

It is assumed that this functional relationship holds for each pairing (firing unit, target unit) over the small time interval dt . The credibility of the model relates the performance characteristic data together with the tactical and physical configurations for each of the combat units to derive the attrition-rate coefficients.

It was decided to express the attrition-rate coefficients as the product of the rate of fire (ROF) and the single shot kill probability ($P(k)$) as follows:

$$\text{Beta}_{DA} = P(k)_{DA} \times \text{ROF}_{DA}$$

where: DA represents a Unit "D" firing on a Unit "A"

More complicated models exist [Refs. 9 and 10], however, for the purposes of the modeling of the ship-to-shore LVA and defender attrition, this method was deemed sufficient.

Attrition-rate coefficients as described above were derived for each pairing (defensive weapon, target) yielding the ten variables:

$$\text{Beta}_{DT-WV(I)} = \text{ROF}_{DT-WV(I)} \times P(k)_{DT-WV(I)} \quad I = 1-5$$

and

$$\text{Beta}_{DS-WV(I)} = \text{ROF}_{DS-WV(I)} \times P(k)_{DS-WV(I)} \quad I = 1-5$$

A switch mechanism is incorporated into the rate of fire (ROF) factor by implementing the functional relationship:

$$\text{ROF}_{D-WV(I)} = \begin{cases} 0 & \text{if WV(I) is located outside} \\ & \text{the engagement window} \\ \\ \frac{1}{\text{TBF}} & \text{if WV(I) is located within} \\ & \text{the engagement window} \end{cases}$$

where: TBF (Time Between Firings) is evaluated by

$$\text{TBF} = \text{Aim-Reload Time} + \frac{\text{Target Range}}{\text{Projectile Velocity} + \text{Target Speed}}$$

It should be noted that the relatively slow projectile velocities representative of anticipated ATGM assets in the future does cause such velocities to become significant in this computation.

The second factor used in determining each attrition-rate coefficient is the single-shot kill probability ($P(k)$). It is assumed

that a hit by a large caliber projectile would constitute a "kill" in that it most likely would inflict damage serious enough either to sink the LVA, or render it immobile, thus eliminating it from contributing to the buildup ashore. A second assumption is that both defensive weapon systems addressed would exhibit normally distributed, uncorrelated horizontal and vertical errors. Typical dispersion data, both mean and standard deviation, for the Tank and ATGM is required as input-data for the hit probability computations.

The suppressive effects of incoming fire upon each of the defensive units was considered a significant factor with respect to its effect upon the survivability of the incoming assault waves of LVA. It was assumed that the suppressive effect would significantly reduce a unit's rate of fire, and also increase the error standard deviation. The modeling of these suppression effects was accomplished by assigning a relative suppression factor (SUPFAC) in the interval 1, 2, to both the Tank and ATGM units. This factor was determined according to the following guidelines:

- | | |
|------------|--|
| SUPFAC = 1 | No incoming fires (i.e., the defensive unit casualty rate is zero) |
| SUPFAC = 2 | Maximum incoming fires (i.e., the defensive unit casualty rate is comparable to that realized upon full allocation of the ATF fire support assets) |

It was assumed that the aim-reload time (ARTM) would be increased by approximately 50 percent under the conditions represented by a SUPFAC = 2.0. Within the ROF submodel, this is expressed by the linear relationship:

$$ARTM_{SUP} = ARTM_{NONSUP} \times (0.5 + SUPFAC / 2.0)$$

Additionally, it was assumed that up to 100 percent increase in the error standard deviation could be expected under a maximum suppression environment, hence:

$$\text{ERROR STD}_{\text{SUP}} = \text{ERROR STD}_{\text{NONSUP}} \times \text{SUPFAC}$$

d. Defensive Breakpoint

It was assumed that if during the course of the ship-to-shore movement phase the defensive forces suffered a cumulative loss in excess of 70 percent of their initial force strength, the remaining shore defenses would withdraw and commencement of the land combat phase of the battle would take place.

5. LVA Assault Wave Conceptualization

The model is programmed to handle up to five incoming waves of LVA. The initial composition of these waves is input by the user by means of the variable WVINT. There are no limitations on the number of LVA's capable of being in each wave. However, the user is advised that the model was intended to model small-unit amphibious operations only.

a. Wave Posture

Model functions RNG, HT, and SPD are called upon within the model logic to generate the range, height, and speed, respectively, for each assault wave as time is incremented throughout the course of the ship-to-shore movement phase. The input of tactical employment parameters TBW and RD in conjunction with the physical design parameters SPDMAX, SPDMIN, HTMAX, and HTMIN for the LVA being evaluated uniquely determines the exact range offshore and vehicle configuration (planning/displacement) for each of the five waves. This information then is implemented in the rate of fire and hit probability calculations.

b. Ground Forces Ashore

As each assault wave arrives at the beach, the surviving strength of that wave is transferred to the variable TLF (Total Landing Force Ashore). TLF represents a ground combat force equal to that transported by the number of LVA survivors having arrived ashore. Once established, the TLF engages the two defensive units allocating its fires between the two defensive weapon categories in the same proportion as the number of surviving Tanks and ATGM's--that is:

$$TLF_{DT} = \frac{DT}{DT + DS} \times TLF$$

$$TLF_{DS} = \frac{DS}{DT + DS} \times TLF$$

The casualty rates applied against the DT and DS state that survivor variables are determined by means of the Lanchester aimed-fire attrition-rate coefficients $WBETA_{TLF - DT}$ and $WBETA_{TLF - DS}$ by the equations:

$$\frac{dDT}{dt} = -WBETA_{TLF - DT} \times TLF_{DT}$$

$$\frac{dDS}{dt} = -WBETA_{TLF - DS} \times TLF_{DS}$$

The computation of these WBETA coefficients is not performed within the model utilizing the detailed rate of fire and P(hit) arguments described previously, since in the original LVA assault model developed by Chadwick, these parameters were considered to be insignificant in relation to the overall model. Chadwick assumed his assault model would be used as an auxillary model to a higher-level model, and would receive values for these coefficients from that model.

6. ATF Fire Support Conceptualization

The impact of the amphibious task force's fire support assets contribute significantly to the combat effectiveness of the shore defense units. Characterizing each of the two defensive force units by a simple "located" or "not located" attribute, the attrition rates realized by these force units can be simplified substantially by the following approach.

a. "Not Located" Shore Defenses

At the commencement of the model it is assumed that the defensive units DT and DS are emplaced on shore at locations unknown to the ATF. The units initially are engaged as "not located" targets by area fire for which the following Lanchester area-fire equations are applicable:

$$\frac{dDT}{dt} = -(\text{ALPHA}_{DT} \times \text{ATFFS}) \times DT$$

$$\frac{dDS}{dt} = -(\text{ALPHA}_{DS} \times \text{ATFFS}) \times DS$$

The terms in parentheses on the right hand side of the equations are to be considered a generalized input parameter. The combat effectiveness of the ATF fire support assets is also to be considered relatively constant during this segment of combat time, and thus it is possible to synthesize these input factors by examining the attrition losses due to area realized in a previous full-scale model calibration run.

b. "Located" Shore Defenses

Once a particular defensive unit has initiated its engagement of incoming waves of LVA it is considered located. At this point it is

assumed that the ATF fire support organization will engage that defensive unit through the use of aimed fire. Again it is assumed that the loss rate will be in accordance with the Lanchester hypothesis for aimed fire, that is:

$$\frac{dDT}{dt} = -\text{Beta}_{DT} \times \text{ATFFS}$$

$$\frac{dDS}{dt} = -\text{Beta}_{DS} \times \text{ATFFS}$$

It should be noted that the right hand side of both of the equations is to be regarded as synthesized factors to be calibrated from a previous high-resolution application.

C. LAND COMBAT PHASE

1. Overview

The land combat phase, like the ship-to-shore phase, has been modeled after broad assumptions have been made concerning the type of forces modeled and force attrition. These assumptions are quite similar in nature to those assumptions made in the ship-to-shore phase of the model which would be expected of similar Lanchester-type combat models.

The first assumption is that of homogeneous forces, which was made as a matter of convenience. The defensive forces will be modeled as a Tube-Launched, Optical-Guided, Wire Controlled missile (TOW) company made up of three TOW platoons located in three separate and fixed defensive positions. Each TOW platoon will be comprised of three TOW sections, and have the capability of withdrawing to an alternate position provided as input by the user. The aggressor force ashore will consist of the

consolidated surviving landing force ashore which has been redistributed into three offensive units.

The second assumption is that the aggressor force units will follow three user-defined routes as they advance toward the three defensive force positions. Routes can be supplied by the user, or defaulted to preassigned routes dictated by the program. However, only three routes can be utilized.

A line of sight (LOS) model written by Professor James Hartman, Naval Postgraduate School [Ref. 11], is used, adding great flexibility to the modeling of the terrain in the basic scenario. This has a direct impact on the probability of detection during any one time period $(t, t+dt)$ which is shown as:

$$P(\text{Unit } i \text{ does not detect Unit } j \text{ in a time period } t+dt) = \frac{P(\text{Unit } i \text{ does not detect Unit } j \text{ in a time period } t, t+dt)}{x}$$

The first two assumptions provide a basis for applying the third assumption which is that attrition of opposing forces will be defined by direct-fire Lanchester differential equations similar to the ship-to-shore phase, only modeled in more detail. Figure 3-7 provides the scheme for the sequence and general flow of events in the model.

2. LVA Movement Conceptualization

a. General

In the original model, aggressor force and defensive force locations were modeled in two different ways. Defensive force locations

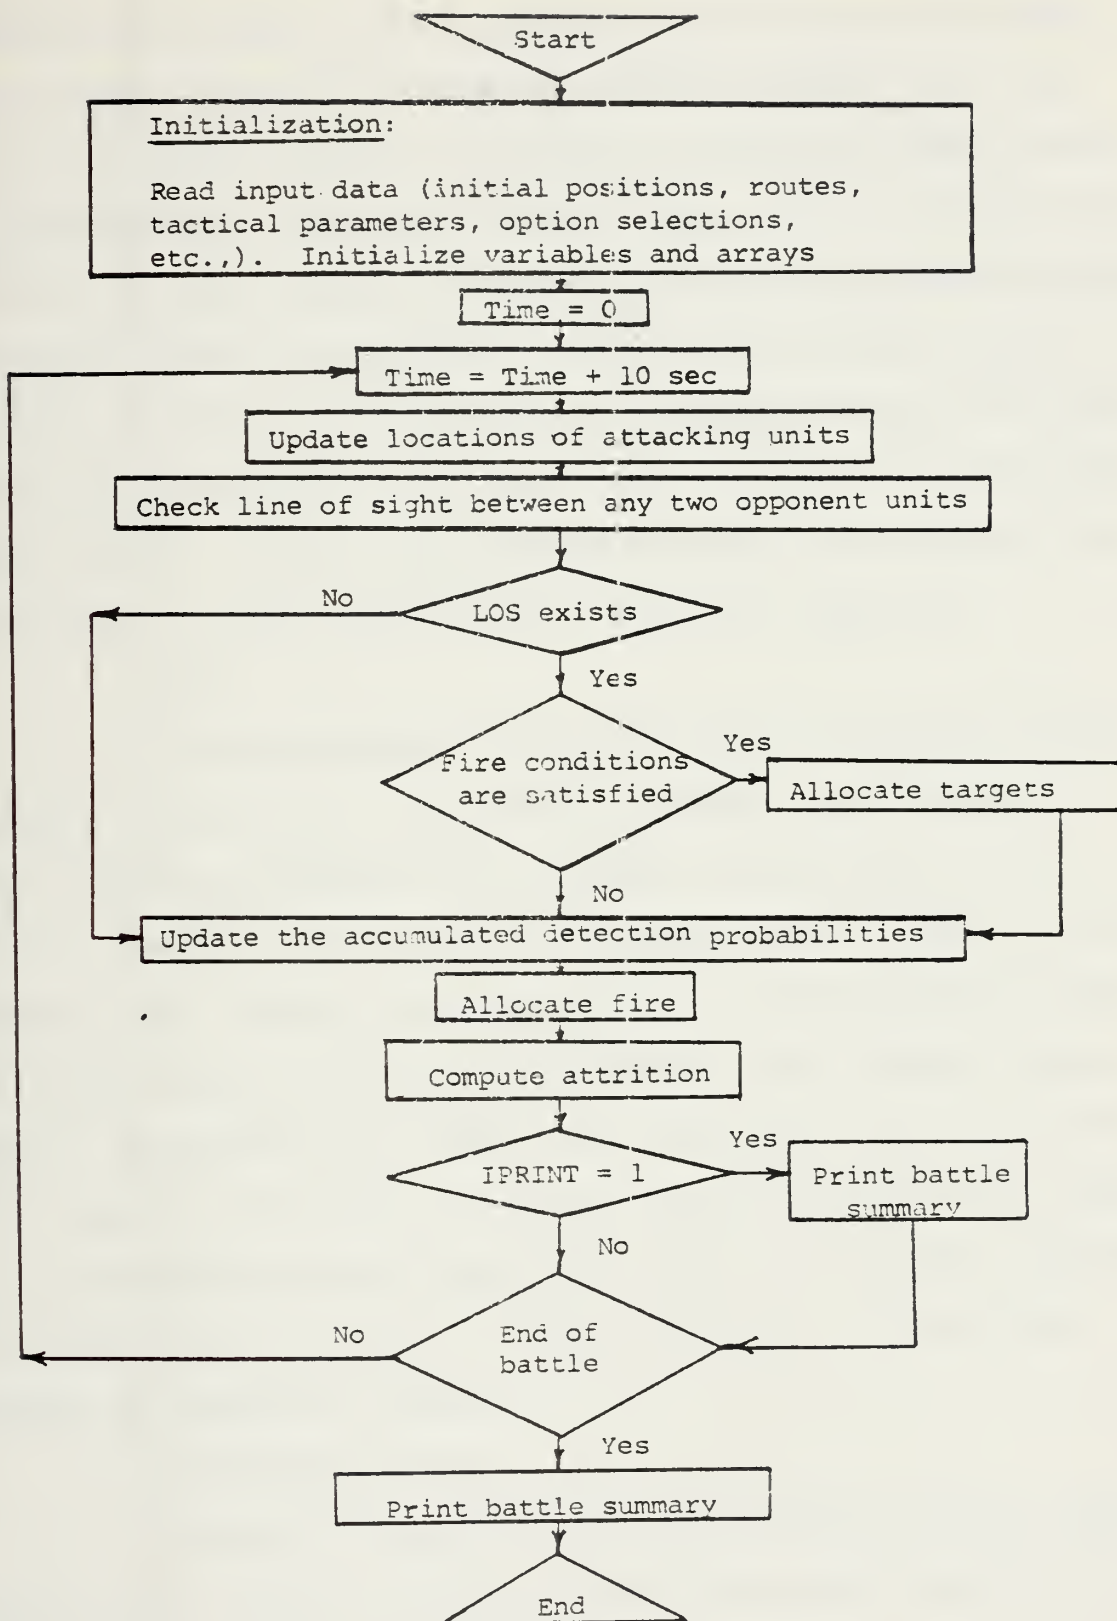

Figure 3-7. Generalized Flowchart for Land Combat

were left as user inputs, whereas aggressor force locations had been predetermined by the model builder, and could not be altered by the user. This allowed a flexibility of modeling defensive positions, but flexibility was limited because of the method of determining movement routes for the aggressors. Glenn Mills provided a user option to the model which permitted the user to model a variety of aggressor force movement scenarios. This option allows for the choice of attack routes and vehicle speed. In addition, the option is highly useful to the unfamiliar user of the model since unit locations and attack routes can be initially set to the model's default values. Different user selected parameters can be input as the user acquires a better understanding of the model's algorithm.

b. Model

Three predetermined routes are provided for aggressor force movements. Each route is subdivided into 40-meter length intervals, since a nonfiring aggressor unit is assumed to move one such interval during a time-step of 10 seconds (i.e., average speed of 9 mph). A firing aggressor unit is delayed a specified number of time-steps before moving to the next interval by the state variable NOD. Each interval in each route is represented by its center point coordinates, and by its direction. If an aggressor unit enters an interval along its associated route, then it is considered to be positioned in the center of the interval, generating a possible location error of ± 40 meters, since this is the distance between two consecutive intervals.

c. User-Defined Routes

The user is required to input the original location of each aggressor unit, and the locations of each of ten nodes he desires the

aggressor unit to move through as it advances on the defensive unit's position. This information, along with vehicle speed, is used to calculate route intervals that move the attacking unit through each of the designated nodes. A complete route would look like that depicted in Figure 3-8. The method used to complete the routes is as follows.

The straight-line ground distance between the first two adjacent nodes (DIST) is calculated as shown in Figure 3-8. The angle between the desired direction of movement and a straight west-to-east movement (α) is then calculated. Utilizing these quantities and the distance desired to be moved during each time-step (DST), the distance to be moved in the X and Y direction (XLN and YLN) is now computed as shown in Figure 3-9. These distances are added to the coordinates of the previous interval endpoint, point C in Figure 3-9, to determine the coordinates of the next interval endpoint, point D. This same distance is again added to compute the coordinates of the next endpoint, Point E. This process is continued until the distance from the last endpoint computed to the next node is less than DST. This general process is repeated for each pair of nodes until the entire route is completed, or the unit's force level is reduced to zero or the battle terminated, whichever comes first.

To insure that all intervals are of equal length, the computation of the first interval between any two nodes must be considered separately by taking into account the distance left over from the last computation between the previous two nodes. To accomplish this, the first interval takes the remaining distance (e) and adds it to an interval length ($DST - e$) for the first interval between any two nodes. This insures that each interval along the route is of length DST, which is the required length.

Figure 3-8. User Determined Routes

<u>NODE</u>	<u>COORDINATES</u>	<u>USE</u>
A	XIC(N-1),YIC(N-1)	(N-1) st Interval Endpoint
B	XLOC(I,J)	User Inputed Node
C	XIC(N),YIC(N)	N th Interval Endpoint
D	XIC(N+1),YIC(N+1)	(N+1) st Interval Endpoint
E	XIC(N+2),YIC(N+2)	(N+2) nd Interval Endpoint
F	XLOC(I,J+1)	User Inputed Node

$$DIST = XL^2 + YL^2$$

$$a = \text{TAN}^{-1} (Y/XL), \text{ where } Y = YL$$

e = distance less than DST at end of calculation of intervals between adjacent nodes.

$$YLN = DST \times \text{SIN}(a)$$

$$XLN = DST \times \text{COS}(a)$$

Figure 3-9. Route Computation

3. LOS, Detection, and Fire Allocation

a. LOS

The existence of a line-of-sight between any two opposing units is determined utilizing a line-of-sight model written and programmed by Professor James K. Hartman, Naval Postgraduate School [Ref. 12], and is listed as Subroutine LOS in the land combat phase of the model. Professor Hartman's model utilizes a parametric terrain model proposed by Needles [Ref. 13], which represented terrain by modeling individual hill masses. Each hill is described by a bivariate normal density function, and fitted together to form a section of terrain utilizing the following information illustrated in Figure 3-10:

- 1) (X_c, Y_c) - Coordinates of each hill's centerpoint
- 2) PEAK - Peak height of each hill
- 3) σ_x - Standard deviation corresponding to the X-axis
- 4) σ_y - Standard deviation corresponding to the Y-axis
- 5) (p) - Rotation factor

Once the terrain has been "mapped", the existence of a line-of-sight can be determined for each pair of opposing units. The information required to accomplish this is the location and elevation of each unit, as well as the height of the vehicle each unit uses. Professor Hartman's model yields the fraction of aggressing Unit A as seen by defending Unit B, and the fraction of defending Unit B as seen by aggressing Unit A. Figure 3-11 is used to illustrate this.

Figure 3-10. Terrain Conceptualization

PORTION OF UNIT A THAT IS VISABLE TO UNIT B

PORTION OF UNIT B THAT IS VISABLE TO UNIT A

Figure 3-11. Partial LOS Conceptualization

b. Acquisition

The acquisition process was well-modeled in the original land combat model devised by Joseph Smoler. The model employs the concept of parallel acquisition, whereby the weapon system continuously searches for targets, even while engaging other targets. When such a weapon system kills its presently engaged target, it immediately can shift its fire to a new target, provided that such a target has been acquired either during the engagement of the previous target just killed, or earlier [Ref. 14]. A general description of the manner in which Smoler modeled target-acquisition is provided here. However, a more detailed description is provided in his thesis.

The probability that a Unit j is detected by a Unit i at time $t+dt$ was modeled for four different combat situations in which the opposing forces might find themselves. These situations can be summarized as follows:

<u>Observer</u>	<u>Target</u>
Not firing ($t, t+dt$)	Not firing ($t, t+dt$)
Not firing ($t, t+dt$)	Firing ($t, t+dt$)
Firing ($t, t+dt$)	Not firing ($t, t+dt$)
Firing ($t, t+dt$)	Firing ($t, t+dt$)

The formulas derived to compute the probability of detection for each of these situations have a number of common variables, therefore their definitions are provided beforehand for clarity:

$P_{ij}(t=dt)$ = The probability that a typical firer in Unit i has acquired one or more targets of type j by time $t+dt$

$$Q_{ij}(t+dt) = [1 - P_{ij}(t+dt)]$$

$$QV_{ij}(t+dt) = e^{-\lambda_{ij}dtS_j(t)}$$

The probability that target j is not visually detected by Unit i during (t,t+dt) provided Unit j does not fire during this time interval

where: $S_j(t)$ = the number of survivors in Unit j at time t

and: λ_{ij} = the nonfiring detection rate of one target in Unit j by one observer in Unit j

$$QP_{ij}(t+dt) = (1 - p_k)^{FR_jdtS_j(t)}$$

The probability that target j is not detected by a launch signature during (t,t+dt) provided that target j fires during this time interval

where: p_k = The probability that one observer in Unit i is looking in a direction which enables him to detect target j

and: FR_j = The firing rate of one firer in Unit j

The first situation occurs when neither the observer nor the target is firing during the interval (t,t+dt). This situation allows the observer to conduct search operations only, thereby maximizing the probability of detecting a target in his sector of responsibility, and has the target maximizing his probability of not being detected by exposure to an observer by a launch signature. Thus, the probability of not detecting in time interval (t,t+dt) is

$$Q_{ij}(t,t+dt) = Q_{ij}(t) \times QV_{ij}(t,dt)$$

The second situation occurs when the target is firing during the search interval $(t, t+dt)$ while the observer is conducting only search operations. This provides the observer with additional information to assist in detection of the target. The observer will detect the target by the target's launch signature. Thus, the probability of not detecting in time interval $(t, t+dt)$ is

$$Q_{ij}(t, t+dt) = Q_{ij}(t) \times (QV_{ij}(t, dt) + QP_{ij}(t, dt) - QV_{ij}(t, dt) \times QP_{ij}(t, dt))$$

The third situation occurs when the observer is firing during the search interval $(t, t+dt)$ while the target is maximizing the probability of not being detected by not firing during the interval. The observer has lowered detection probability by diverting a portion of his force to firing on a known target. A new factor is introduced which will alter the probability of detection, namely the event:

A = The situation in which Unit j is within the field of view of Unit i, with at least one of the targets at which Unit i is firing

This states that Unit j, which is not currently firing, happens to expose itself to firing Unit i when firing Unit i is looking and firing on at least one other target in j's principal direction. Thus, the probability of not detecting in time interval $(t, t+dt)$ is

$$Q_{ij}(t, dt) = \begin{cases} 0 & \text{if event A occurs} \\ g(n) & \text{if j is an aggressor unit and event } \bar{A} \text{ occurs} \\ Q_{ij}(t) & \text{if j is a defending unit and event } \bar{A} \text{ occurs} \end{cases}$$

where: $g(n)$ is an increasing function of n ,
where n is the number of time intervals
elapsed since time t .

and: $g(0) = Q_{ij}(t)$

$$Q_{ij}(t) \leq g(n) \leq 1.0 \text{ for all } n$$

The fourth situation occurs when both the observer and target are firing during the interval $(t, t+dt)$. In this situation the observer has minimized his searching capability, and the target has maximized its probability of being detected. Thus, the probability of not detecting in time interval $(t, t+dt)$ is

$$Q_{ij}(t, t+dt) = \begin{cases} Q_{ij}(t) \times QV_{ij}^*(t, dt) & \text{if event A occurs} \\ g(n) & \text{if } j \text{ is an aggressor} \\ & \text{unit and event } \bar{A} \text{ occurs} \\ Q_{ij}(t) & \text{if } j \text{ is a defender unit} \\ & \text{and event } \bar{A} \text{ occurs} \end{cases}$$

where: $QV_{ij}^*(t, dt) = e^{-\lambda_{ij}^* dt S_j^*(t)}$

and: $\lambda_{ij}^* = i_{ij} \times RF$

RF = Reduction Factor (the detection rate of Unit i has to be reduced since this unit fires during $(t, t+dt)$ and the search for targets is not as effective as for a nonfiring unit)

$$S_j^*(t) = S_j(t) \times \left(\sum_k PTT_{iK} \right)$$

PTT_{iK} = proportion of Unit i allocated to Unit K

k = (Unit K is engaged by Unit i and Unit j is within the field of view of Unit i while observing Unit K)

If a line-of-sight does not exist between observer i and target j , then no accumulation of detection probability will take place during the current time interval (i.e., $P_{ij}(t)$ will remain the same). However, if a line-of-sight does not exist throughout more than three consecutive time intervals, then the P_{ij} is set to zero (i.e., $P_{ij}(t) = 0$) and the accumulation process will start again from zero if a line-of-sight is acquired at a later point in the battle. The motivation for this decision rule is seen by the observation that even if observer i loses a line-of-sight with target j for a short period of time, he still probably has some idea of where to expect the target to reappear.

c. Non-Firing Detection Rate

The situations that occurred when the target was in a non-firing status had detection probability functions that had as a parameter λ_{ij} , a non-firing detection rate. The manner in which the model derives this rate is quite detailed, and deserves attention.

To begin, each firer in an observing unit is assigned a search section (or sector of responsibility) which is characterized by two parameters (see Figure 3-12). These parameters are the section width (ISECWD), and the primary direction of search (IPRDIR). Furthermore, it is assumed that the search direction within a section of search has the following probability density function known as the LIMICON Function:

$$f(\theta) = A + B \cos \theta \quad -D \leq \theta \leq D$$

$$\text{where: } D = \text{ISECWD}/2$$

$$A = -B \cos D$$

$$B = \frac{1}{2 (\sin D - D \cos D)}$$

Figure 3-12. Search Direction

Figure 3-13. Observer-Target Scheme
(A = Observer, B = Target)

$\theta = \emptyset$ corresponds to the observer's primary direction of search

note: A and B are chosen such that

$$\int_{-D}^D f(\theta) d\theta = 1$$

To determine the probability that observer A is looking in a direction which enables him to detect target B, P_k is the value of the LIMICON function integrated from an angular value up to 15° on either side of the primary direction of fire, specifically:

$$P_k = \int_{\text{ANGRT}}^{\text{ANGLFT}} f(\theta) d\theta = \text{shaded area, Figure 3-13}$$

$$\text{where: } \text{ANGLFT} = \begin{cases} \text{ANGLE} + 15^\circ & \text{if } \text{ANGLE} + 15^\circ \leq D \\ D & \text{if } \text{ANGLE} + 15^\circ > D \end{cases}$$

and: ANGLE = the absolute value of the angle between the primary direction (IPRDIR) and the observer-target direction (OTANG)

$$\text{ANGRT} = \text{ANGLE} - 15^\circ$$

Now, given that observer A is looking in a direction α such that $\text{ANGRT} \leq \alpha \leq \text{ANGLFT}$, the conditional detection rate ($\lambda_{ab} \mid \text{ANGRT} \leq \alpha \leq \text{ANGLFT}$) is determined by a regression curve [Ref. 15] which is a function of the terrain, target horizontal velocity, and the equivalent range for a full height target. This detection rate of one observer detecting one target becomes

$$\lambda_{ab} = (\lambda_{ab} \mid \text{ANGRT} \leq \alpha \leq \text{ANGLFT}) \times P_k$$

d. Fire Allocation

Three conditions are necessary for Unit j to be classified as a target for Unit i . First, a line-of-sight must exist between Unit i and Unit j . Second, the range between the units must be within the maximum range of Unit i 's weapon system. Lastly, the probability that a detection of Unit j is made by an observer in Unit i in the time period $t+dt$ must be greater than 0.00.

Once these conditions are satisfied, the manner in which fire is allocated to a target depends upon how many targets are to share in the firepower of Unit i , and what distance exists between i and the new target in relation to the other targets under fire. The priority of fire naturally will go to the closest target since it is of a greater threat to Unit i than the more distant targets. The amount of firepower available from Unit i is naturally a function of the percentage of surviving force available to fire in Unit i .

4. Attrition

Attrition of forces is assessed based upon variable coefficient Lanchester equations of modern warfare [Ref. 16]. This method of attrition assessment was used by David Chadwick in the ship-to-shore phase of the model, however, in less detail than was modeled by Joseph Smoler in the land combat phase of the model. The "extra" detail provided by Joseph Smoler is the generation of the conditional probability of a kill given a hit. This probability was stated by Chadwick as a user-supplied input parameter.

The restriction of the model to aimed-fire weapons systems and homogeneous forces allows for the attrition of forces to be assessed using variable coefficient Lanchester equations of modern warfare.

The attrition for a defending Unit j is described by the following differential equation:

$$\frac{dS_j(t)}{dt} = -(A_{ij} \times \text{PROP}_{ij}) \times S_i(t)$$

where: $S_k(t)$ = The number of survivors in Unit k at time t

A_{ij} = The rate at which one firer of Unit i kills Unit j targets (attrition rate of Unit j by one firer of Unit i)

PROP_{kl} = Proportion of Unit k allocated to fire against a Unit l

These basic differential equations of force-on-force attrition were approximated by the following Euler-Cauchy difference equations:

$$S_i(t+dt) = \text{Max}(0, S_i(t) - \sum A_{ji}(S_j(t) \times \text{PROP}_{ji})dt)$$

for each defending Unit i

and:

$$S_j(t+dt) = \text{Max}(0, S_j(t) - \sum A_{ij}(S_i(t) \times \text{PROP}_{ij})dt)$$

for each aggressor Unit j

The manner in which the attrition-rate coefficient A_{ij} is derived stochastically already has been discussed in the model enhancement chapter, therefore, only a description of how the deterministic attrition-rate coefficient is derived will be mentioned here.

The attrition-rate coefficient, A_{ij} , for each equation is computed according to the equation:

$$A_{ij} = \frac{1}{E[T_{ij}]}$$

where: T_{ij} = the time for one firer of Unit i to kill one target of Unit j under the conditions in the present time interval

T_{ij} is computed using the Bonder-Farrell formula [Ref. 17]:

$$E[T_{ij}] = t_a + t_1 + \frac{t_h + t_f}{P(k|h)} + \frac{1 - P(h|h)}{P(k|h)} + P(h|h) - P(h)$$

where: t_a = Time to acquire a target
 t_1 = Time to fire first round after a target is acquired
 t_h = Time to fire a round following a hit
 t_m = Time to fire a round following a miss
 t_f = Projectile's time of flight
 $P(h)$ = Probability of a hit on first round
 $P(h|h)$ = Probability of a hit on a round given that the prior round fired was a hit
 $P(h|m)$ = Probability of a hit on a round given that the prior round fired was a miss
 $P(k|h)$ = Probability of a hit on a round given that the round fired was a hit

There are two assumptions of the Bonder-Farrell formula that are implied by the model. The first assumption is that fire is Markov-Dependent in that the probability of a hit of any round depends only upon the result of the previous round. The second assumption is that a Geometric Distribution describes the parameter $P(k|h)$ in that accumulated damage is considered to be negligible.

The expected value of T_{ij} , $E[T_{ij}]$, may now be expressed for each weapon system in the model. It is assumed that for the TOW

weapon system $P(k|h) = 1.0$, and $P(h|m) = P(h|h) = P(h)$, which results in the reduced formula:

$$E[T_{ij}] = t_a + t_l + t_f + \frac{(t_m + t_f) \times (1 - P(h))}{P(h)}$$

If the firing weapon system is a tank, then it is assumed that $P(k|h) = 1.0$ (due to a lack of information), and that $t_f = 0.0$ (due to the velocity of the projectile). Thus, in this case the formula becomes:

$$E[T_{ij}] = t_a + t_l + \frac{t_m}{P(h|m)} \times (1 - P(h))$$

It should be noted that all targets were considered to be stationary throughout the attrition process. This is obvious in the case of the stationary defending forces, and was assumed to be the case for the aggressor forces due to the fact that the hit probability of a TOW against a moving target is almost the same as for a stationary target.

5. Battle Termination

Two criteria were used as rules governing battle termination. The first criterion was the annihilation (zero force level) of one of the two forces. The second criterion was that the distance between defender and aggressor forces is too small.

The first criterion is an intuitively obvious reason for terminating the battle, and thus easy to model. However, although the reasons for the second criterion might be as obvious, the modeling of this is not simple. The manner in which Glenn Mills modeled it was to compute the distance between each attacking sub-unit on which casualties were being assessed (i.e., still alive), and each defending

sub-unit that was still alive. If any one of these distances between active sub-units was too close, the battle was considered to have reduced to close-in, hand-to-hand combat. The outcome of this type of combat is not currently provided for in the model, and for this reason the battle is simply terminated at this point. However, to insure that the aggressor units do not pass by the flanks of the remaining defending forces and remain outside termination distance, a check is made of the location coordinates of each sub-unit. If any aggressing sub-unit's X coordinate places the unit beyond the location of the most forward defending sub-unit still in the battle, the battle also is terminated.

The specification of the distance between forces for battle termination is left as a user-input, which provides added flexibility of breakpoint distance analysis. In particular, it lends itself to the study of optimum breakpoint distances for various weapons systems on the battlefield.

IV. FUTURE ENHANCEMENTS

A small-unit amphibious operation combat model has been presented in this thesis which emphasizes the simplistic and avoids the abstract to provide an understandable and, more importantly, a useable combat model for students of combat modeling. However, the combat model presented has the potential of being developed into a much more refined model which could be studied and utilized by more experienced combat modelers. Therefore, several enhancements which might be of some benefit to the more experienced modeler are mentioned here as possible approaches that could be taken in refining the present model.

A. HETEROGENEOUS FORCES IN THE LAND COMBAT PHASE

The current land combat phase of the model involves combat between homogeneous forces only--that is, each force is comprised of only one weapon system type. This type of force structure was intentionally modeled to maintain a relatively simple model to understand and work with. However, added flexibility could be attained by modeling multiple weapons system types for each of the opposing forces. This would allow the user to analyze the effect that different force mixes would have on battle outcome.

The addition of different weapons system types within a single unit would require extensive restructuring of the attrition process currently used in this model. Although Lanchester equations still could be utilized in computing direct-fire weapon system attrition, separate Lanchester equations would have to be provided for each weapon system.

Furthermore, with the addition of indirect-fire weapon systems (i.e., artillery, naval gunfire, and close air support) Lanchester equations for area-fire would have to be implemented for each area-fire weapon system type. The total attrition of any particular unit then would be the summation of the damage assessed by each weapons system type on the target being attrited.

An enhancement of this type would result in more realism at the cost of longer execution time, and a more complicated attrition process. Since the original intent of the thesis was to provide a simple model to understand, it would be advisable to retain a copy of the original model prior to adding this enhancement. Then a simple model would still be available to the less experienced combat modeling students, while a more detailed model would provide the realism that more experienced modelers would demand.

B. LOGISTICAL SUPPORT

Logistical support is one of the most overlooked factors of combat in the development of combat models. The influence that the resupply of fuel and ammunition alone have on the outcome of a battle is obvious and deserves attention.

Ammunition and fuel consumption could be modeled along the same lines as attrition (i.e., through the use of expected values of consumption). When ammunition or fuel on hand reaches a specified critical level, a unit could be restricted in movement, or experience a reduced level of fighting effectiveness and maneuverability (based on a shortage of ammunition and fuel) until resupply of the critical resource could be obtained.

The amount expended of these resources would necessarily be a function of the number of surviving firers in the unit, the number of vehicles available to transport the unit, and the number of targets engaged by the unit at any one time interval. The expected values of these items then could be used in computing the expected rate of consumption of ammunition and fuel. Therefore, the overall process could be modeled by initially allocating specific levels of these resources (i.e., ammunition and fuel) to each unit at the commencement of the battle, and subtracting the expected expenditure of the ammunition and fuel of a particular unit based upon the expected number of survivors firing on engaged targets, and the distance traveled by the expected number of surviving vehicles of the unit.

C. GRAPHICAL BATTLE SUMMARY

A graphical display of what is taking place on the battlefield can be worth a thousand words to the user of a combat model. Plotting unit locations and force levels on a display of the actual terrain fought upon would eliminate time-consuming interpretation of these results from a printed battle summary report. An enhancement of this sort would serve both the experienced and inexperienced users of the model. The inexperienced user would have results displayed in a much more understandable format, while the experienced user would be able to study variant combat scenarios with much less effort and time expended.

V. FINAL REMARKS

The purpose of the model that has been developed is to illustrate a number of underlying concepts of combat modeling which have been addressed in this study. Therefore, it seems appropriate to readdress these concepts to allow the reader to reflect upon them in light of what has just been presented.

A. INTEGRATING INITIALLY INDEPENDENT COMBAT MODELS

The model developed here was made up of two sub-models: ship-to-shore and land combat models. These sub-models, as discussed earlier, utilized similar combat modeling methodology (i.e., Lanchester equations) in computing force level attrition. However, each sub-model was developed by different individuals, which created several problems when the two separate sub-models were integrated into a singular continuous flow algorithm. In particular, individualized FORTRAN coding techniques and documentation of state variables within the program structure required the restructuring of major portions of FORTRAN code to make the overall combat model tractible and understandable. This serves to illustrate the need for a standardized programming technique to be applied to programming of combat models, and highlights the need for proper planning and coordination in development of large scale combat models by teams of combat modelers.

B. THE USER-ORIENTED APPROACH TO COMBAT MODELING

This thesis illustrates the desirability of a user-friendly approach to combat modeling. It was a major contention of the thesis

that this approach to combat modeling has not been closely addressed by combat modelers providing combat models for the United States military. Furthermore, it was mentioned that the lack of concern given to this approach of combat modeling might help to explain the lack of enthusiasm exhibited by the United States military in utilizing combat models for the training of field commanders and staffs. The thesis had as one of its purposes, the presentation of a combat model designed to be easily understood and utilized by intended users, combat modeling students. Combat models should be designed and documented with the user's capabilities and needs in mind, as opposed to those of the programmer.

C. A COMBAT MODEL FOR STUDENT USE

The small-unit amphibious operation combat model presented here is a basic Lanchester-type combat model which has been designed with a low level of complexity in order that it might be understood more easily, and studied by students of combat modeling. It has been recognized that combat modeling students may have little or no experience of the governing theory, and therefore would comprehend the theory of combat modeling more easily by utilizing and understanding its basic application. For this reason, enhancements that would increase the complexity of the model are discouraged, and enhancements that would make the model more understandable (i.e., graphical battle summary reports) are strongly encouraged.

I. INTRODUCTION

The purpose of this manual is to familiarize the user with the model, and to provide administrative information describing how the potential user would access and run the model.

The small-unit amphibious operation combat model is a two-phased combat model which conducts both ship-to-shore and land combat. The model uses both aimed and area-fire Lanchester-type equations for casualty assessment. The battle is initiated by an amphibious task force positioned 25 miles offshore from an opposing defensive force which is illustrated in Figure A-1. If an amphibious landing is successful, land combat will be conducted inland over a 10 x 10 km piece of terrain representing an area east of Fulda, West Germany, known as the Fulda Gap, which is depicted in Figure A-2.

Figure A-1. LVA Approach Conceptualization

Figure A-2. Land Combat Terrain Model

II. AVAILABLE OPTIONS

The model has been developed with a number of options available to the user to provide more model flexibility for the more experienced user. Each of these options, including user responsibilities, is discussed here with the input requirements for each being outlined in the next section.

A. STOCHASTIC VS. DETERMINISTIC ATTRITION

The user has the option of using stochastic or deterministic attrition computation. Both methods utilize Lanchester aimed-fire equations; the difference between the two is the method of calculating the attrition-rate coefficients used in the Lanchester equations.

Deterministic attrition can be thought of as the expected value of attrition, and is implemented by using the Bonder-Farrell method of calculating the attrition-rate coefficient, A_{ij} . The stochastic method can be thought of as the randomization of attrition, and is implemented by using random deviates from a Beta Distribution in conjunction with the range of a target to generate individual attrition-rate coefficients for each unit at each time-step.

B. VARIANT ATTACK ROUTES

The user has the option of providing variant aggressor force attack routes. The user can utilize the program's straight west-to-east routes, or can input desired altered routes for aggressor force units to follow. To select new routes, a user must input the number of nodes desired on

each of three routes, and the coordinates of each of these nodes. The program then will compute routes through each node. The nodes must be inputted in order from west to east, and should not create an angle between the west-to-east axis and the route direction that exceeds 45°.

C. ALTERNATE DEFENSIVE POSITIONS

The user has the option of implementing alternative defensive unit locations. This option permits the user to add more realism to the model by allowing the defending units to withdraw to alternate positions when their primary positions become untenable (i.e., distance between opposing forces is too close). This breakpoint distance is determined and inputted by the user, and also is used as the distance for battle termination in the event that the battle reduces to close-in combat (i.e., hand-to-hand). The alternative to moving the defenders is to terminate the battle when the breakpoint distance is initially reached.

D. BATTLE SUMMARY PRINT-OUT

The user has the option of limiting the printed output of the model. The user can receive a battle summary print-out at the completion of each 10-second time interval, or this information can be suppressed, printing out the results only after each phase of combat.

III. REQUIRED INPUT

The small-unit amphibious operation combat model presented in this thesis has been provided with a blank data set (see Appendix D) which includes each variable of the model requiring input provided by the user, and space available following each variable for the user to place the desired variable value. However, the definition of each input variable may not be familiar to the first-time user of the program. Therefore, the following list of input variables and their definitions is provided as a quick reference for the user of the model.

Ship-to-Shore Phase

<u>Input Variable</u>	<u>Definition</u>
IPRINT	User option for selecting type of battle summary report desired: 0 - Each Time-Step 1 - End of Battle
SPDMAX	Maximum speed of LVA in the water.
SPDMIN	Minimum speed of LVA in the water.
HTMAX	Height of LVA above water at maximum speed.
HTMIN	Height of LVA above water at minimum speed.
WIDTH	Width of an LVA.
TENGMX	Tank maximum engagement range.
SENGMX	ATGM maximum engagement range.
SENGMN	ATGM minimum engagement range.
TARTM	Tank aim-reload time.
SARTM	ATGM aim-reload time.

<u>Input Variable</u>	<u>Definition</u>
TVEL	Tank projectile velocity.
SVEL	ATGM projectile velocity.
TSIGV	Standard deviation error in the vertical axis for Tank fire.
TSIGH	Standard deviation error in the horizontal axis for Tank fire.
TMEANH	Bias error in the horizontal axis for Tank fire.
SSIGV	Standard deviation error in the vertical axis for ATGM fire.
DEFWTS	Defensive force tactical allocation weights.
WVINT(i)	Initial strength of assault wave I.
DINIT(i)	Initial strength of defensive Tank (I=1) and ATGM (I=2) units.
A(i)	Aggressor force attrition coefficients.
B(i)	Defensive force attrition coefficients.
WB(i)	Aimed-fire attrition-rate coefficients for defensive force Tank and ATGM units.
GAINL	Defensive force attrition level at which remaining defending forces withdraw and ground assault commences.
GAMMA	Aim-reload time suppression factor.
DELTA	Aiming error caused by the suppression factor of ATFFS

The remaining portion of the input data refers to the terrain model developed by Professor James Hartman. It is suggested that this portion of the data set not be altered until the user has studied and fully understands the Hartman terrain model.

Land Combat Phase

<u>Variable</u>	<u>Definition</u>
ITRIT*	Input variable denoting whether attrition will be stochastic or deterministic: 0 - Stochastic 1 - Deterministic
DSEED**	Double precision seed used in the Beta Distribution Random Deviate Generator.
PP - QQ PD - QD	Input parameters for the Beta Distribution Random Deviate Generator: PP-QQ Aggressor force PD-QD Defensive force
NBU	Number of defensive units.
NRU	Number of aggressor units.
RMINTK	Minimum effective range of an LVA weapon system.
RMAXTK	Maximum effective range of an LVA weapon system.
RMINTW	Minimum effective range of a defensive TOW weapon system.
RMAXTW	Maximum effective range of a defensive TOW weapon system.
IRTE	User option for selecting type of aggressor force attack routes: 0 - Program determined 1 - User determined
ISPD	Speed of aggressor force units: 1 - 9 MPH 2 - 12 " 3 - 15 " 4 - 18 "
XIC(i,j), YIC(i,j)	Coordinates of the j th interval endpoint of the route for Unit i.
N(i)	Number of nodes for aggressor route i.

Note: *There are two ITRIT variables in the data set. The first ITRIT refers to the aggressor forces.

**There are two DSEED variables in the data set. The first DSEED refers to the aggressor forces.

<u>Variable</u>	<u>Definition</u>
XLOC(i,j),YLOC(i,j)	Coordinates of node i for aggressor route i.
X(i),Y(i)	Location of defensive Unit i.
FL(i)	Force level of a defensive Unit i.
IPRDIR(i)	Principal direction of fire of defensive Unit i.
IALT	User option for selecting alternate defensive positions: 0 - Yes 1 - No
BREAK	Breakpoint distance between aggressor units and defensive units.
ITEM	Input variable denoting number of time-steps allowed for aggressor unit moves.
XA(i),YA(i)	Coordinates of alternate position for defensive Unit i.
P(i,j)	Probability of first round hit by Unit i in range band j.
PHH(i,j)	Probability of a hit following a hit by Unit i in range band j.
PHM(i,j)	Probability of a hit following a miss by Unit i in range band j.
PKH(i,j)	Probability of a kill given a hit by Unit i in range band j.

IV. EXPECTED OUTPUT

The small-unit amphibious operation combat model's output is designed to be self-explanatory. Each phase of the amphibious operation is reported in the output of the model. The output format for each phase will include an initial information section to provide the user with feedback concerning the operation of the model as read-in by the model from the user-supplied input data. This serves as a check and a record for the user to insure that the model was run according to the intended design of the user. Secondly, battle summary reports are provided at specific points of the battle depending upon the desires of the user as input by the user option variable IPRINT. An example of the model's output is displayed in Appendix F.

V. ACCESSING AND EXECUTING THE MODEL

The prospective user who wishes to study the small-unit amphibious operation combat model must first contact Professor James Taylor of the Operations Research Department and obtain the user identification number and password for the disk space containing the model and its support programs.

A. ACCESSING THE MODEL

Once the required information is obtained, the user should proceed to LOG ON to his OWN disk space entering the CMS mode of operation.

Upon entering CMS, the following commands should be executed:

LINK TO (USER ID*) 191 AS 192 RR

PASSWORD

ACCESS 192 B/A

COPYFILE AMPHIB FORTRAN B = = A

COPYFILE SEA DATA B = = A

COPYFILE LAND DATA B = = A

COPYFILE BSEA DATA B = = A

COPYFILE BLAND DATA B = = A

COPYFILE WAR EXEC B = = A

RELEASE 192 (DET

*Note: USER ID refers to the user id provided by Professor Taylor.

What is received on the user's disk is a copy of the following files:

1. The Small-Unit Amphibious Operation Combat Model (APPENDIX B).
2. A complete data set: SEA and LAND (APPENDIX C).
3. A blank data set: BSEA and BLAND (APPENDIX D).
4. The model's executive program: WAR (APPENDIX E).

B. EXECUTING THE MODEL

To execute the model utilizing the data set provided, the user must first compile the FORTRAN program, AMPHIB, by entering the following commands:

```
DEF STOR 1M
```

```
I CMS
```

```
FORTGI AMPHIB
```

Once the program is compiled, the user enters the name of the executive file WAR, which then executes the program and displays the listing file of output from the model, (i.e., AMPHIB1 LISTING (APPENDIX F)) in the BROWSE mode of XEDIT.

C. ALTERING THE DATA SET

The user may desire to invoke one of the available options provided, or alter specific elements of the existing data set to "play out" various combat scenarios. To alter the existing data set, the user first decides whether to alter the ship-to-shore phase of combat, or the land combat phase. Once this has been established, the user can simply XEDIT the appropriate data file, replacing the old input data with the new input data.

To construct an entirely new data set, the user should make use of the blank formatted data set provided. The user simply XEDIT's the

BSEA or BLAND data files, inputting new data by typing over the spaces provided. The variable names are listed in both of the data sets, as well as in Chapter III of this user's manual. The space provided in the blank data sets is designed to be compatible with the READ format statements of the program.

D. EXECUTING THE MODEL AFTER ALTERING DATA

If the user has just altered specific elements of the data set provided without altering file names, the user will once again enter the name of the executive file WAR, and enter the new data set file names where appropriate. Once this editing of the executive file has been accomplished, the user simply enters the executive file name WAR to execute the model again.

VI. PROGRAM STRUCTURE

The small-unit amphibious operation combat model is a computerized model written in FORTRAN. It consists of a main program and 19 sub-routines. To assist the user in understanding the operation of the model, a brief description of the function of each subroutine, as well as the functioning of the main program, is provided.

A. MAIN PROGRAM

The main program serves as a director program for the model. It calls for the initialization of data for the ship-to-shore phase of combat, and then commences the execution of that phase of combat. The results of the ship-to-shore phase of combat as provided by subroutine SEA are then reviewed to determine if the land combat phase of combat should begin, or if the battle should be terminated. If the results warrant a continuation of the battle, the reason for continuation is printed and land combat is initiated.

B. SUBROUTINES

There are 19 subroutines in the model. The function of each has been provided at the beginning of each subroutine in the coded program, and also is presented here for clarity.

1. Subroutine SEA

This subroutine is the main driver program for the ship-to-shore phase of the amphibious operation. Its main purpose is to initialize key parameters, and to direct program flow in the ship-to-shore phase of combat.

2. Subroutine RKINT

This subroutine provides the interface between the EULER numerical integration routine (RKLDEG) and the subroutine ATTR which determines each unit's status as time progresses throughout the amphibious operation.

3. Subroutine ATTR

This subroutine determines the attrition rates and updates the status of each unit with respect to shore movement based upon the given state variable strengths, and implements this information into the attrition loss-rate computation.

4. Subroutine DTGTS

This subroutine determines the wave numbers that are to be engaged by the defensive Tank and ATGM units, based upon the engagement window criteria and LVA wave survivor force levels.

5. Subroutine DATAIN

This subroutine reads in all user-supplied information required by the ship-to-shore phase of the model.

6. Subroutine OUTPUT

This subroutine provides an input summary printout based upon the data received by subroutine DATAIN. A printout of dispersion data generated as a result of data supplied also is provided.

7. Subroutine PHIT

This subroutine computes the probability of a hit based upon the range, width, and height of a given target. The type of weapon being employed against the target then is taken into consideration for computing the specific probability of a hit.

8. Subroutine INTRP

This subroutine is a check to insure that the range of a target and the dispersion data are compatible for computing the probability of a hit in subroutine PHIT.

9. Subroutine RATE

Given the range and speed of a target, along with the type of weapon being used to fire upon the target, and the suppression factor the firer is being subjected to, subroutine RATE computes the rate of fire used against a particular target.

10. This is the primary subroutine of the land combat phase of the amphibious operation. Information required for the operation of the land combat phase is read-in and printed in a summary table for user review. The information provided by all other subroutines used in the land combat phase is used in this subroutine as input to the basic land combat algorithm.

11. Subroutine SETUP

This subroutine is used to read-in the terrain data and create parametric terrain. The terrain data will be used when computing line-of-sight between targets and observers, as well as providing a grid system for unit locations and movement.

12. Subroutine ROUTE

This subroutine computes the route of each aggressor unit when the user has selected the option of inputting aggressor routes. It calculates the coordinates of each interval endpoint along the route, making each interval length (distance moved during a ten-second time-step) the same. The interval length is determined by the speed the user has selected and inputted for the current battle.

13. Subroutine LAMBDA

This subroutine used in conjunction with the line-of-sight routine computes the detection rate (DETRAC) of target j by the observer i, given the percent of target visible (PCTVIS) to the observer.

14. Subroutine ELEV

This subroutine determines the terrain elevation for a given set of X, Y coordinates. This function is used in conjunction with the line-of-sight subroutine in computing a line-of-sight between observer and target.

15. Subroutine STOCH

This subroutine determines the attrition coefficients when a user has selected a stochastic attrition option. The calculation is a function of the original stochastically determined attrition coefficient, as well as a function of range.

16. Subroutine ETK

This subroutine computes the expected time for a given firer to kill a given target. The calculation is a function of range, time of flight for a round, and hit and kill probabilities for the firing weapon system. It is a number that is used in computation of the deterministic attrition coefficients.

17. Subroutine SORT

This subroutine is used to sort targets in ascending range order. This is used to determine the priority of a target for fire allocation.

18. Subroutine KOVER

This subroutine determines what portion of a particular target is covered by the terrain between the target and observer.

This number is used both in the detection of the target, and in the attrition computation.

19. Subroutine LOS

This subroutine was written by Professor James Hartman, Naval Postgraduate School. It computes a percent of a target visible to a particular observer, given the location coordinates of both.

VII. DEFINITION OF VARIABLES IN COMPUTER PROGRAM

A. VARIABLES USED IN THE SHIP-TO-SHORE PHASE

A(i)	Aggressor force attrition coefficients.
ATFFS	Amphibious Task Force Fire Support.
B(i)	Defensive force attrition coefficients.
CDSURV(i)	Current strength of defensive Unit i: 1 - Tank 2 - ATGM
CSURVE(i)	Current strength of assault wave i.
DA(i)	Attrition rate for defensive Unit i due to the effects of ATFFS/TLF.
DEFWTS	Defensive Force Tactical Allocation Weights.
DELTA	Aiming error caused by the suppression factor of ATFFS.
DINIT(i)	Initial strength of defensive Unit i.
DS1	That portion of the defensive force ATGM unit assigned to engaging the closer of two multiple waves in the ATGM engagement window.
DS2	That portion of the defensive force ATGM unit assigned to engaging the farther of two multiple waves in the ATGM engagement window.
DT1	That portion of the defensive force Tank unit assigned to engaging the closer of two multiple waves in the Tank engagement window.
DT2	That portion of the defensive force Tank unit assigned to engaging the farther of two multiple waves in the Tank engagement window.
DT1PH	Hit probability of rounds fired by DT1 against the assault wave in its engagement window.

DT1ROF	Rate of fire utilized by DT1 against the assault wave in its engagement window.
GAINL	Defender attrition level at which remaining defending forces withdraw and land combat commences.
GALF	Denotes whether the landing force buildup is sufficient for land combat: 0 - Insufficient 1 - Sufficient
GAMMA	Aim-reload time suppression factor.
GATK	Denotes whether the landing force has initiated the land combat: 0 - Not started yet, 1 - Started already.
GATM	Time at which land combat commenced.
IL(i)	Denotes if wave i has reached the shore: 0 - Wave i not ashore, 1 - Wave i ashore.
IPRINT	Denotes whether the user desires battle summary at each time-step, or just a final summary: 0 - Battle summary printed after each time-step, 1 - Final battle summary only.
IWPH	Weapon-type code: Tank = 1, ATGM = 2.
IWSTAT(i)	Current status of assault wave i: 0 - Not engaged, 1 - Landed, 2 - Under fire by ATGM, 3 - Under fire by Tank, 4 - Under fire by both ATGM and Tank.
RD	Distance offshore at which waves initiate their transition.
RKSURV(i)	Concatenation of CSURV and CDSURV.
SA(i)	Attrition rate for wave i due to ATGM.
SARTM	ATGM aim-reload time.
SENG(i)	Wave number of the closer of two assault waves in the ATGM engagement window.

SENGMN	ATGM minimum engagement range.
SENGMX	ATGM maximum engagement range.
SRNG(i)	Firing range to wave SENG(i).
SSIGH	The standard deviation error in the horizontal axis for ATGM fire.
SSIGV	The standard deviation error in the vertical axis for ATGM fire.
SVEL	ATGM projectile velocity.
SWTS(i)	The proportion of the total defensive force ATGM strength to be allowed to engage wave SENG(i).
TA	Time first assault wave initiates its transition.
TA(i)	Attrition rate for assault wave i due to Tank fire.
TARTM	Tank aim-reload time.
TB	Time first assault wave completes its transition.
TBW	The interarrival time between waves arriving at the beach.
TFF	Time first assault wave reaches the beach.
TENG(i)	Wave number of the closer of two assault waves in the Tank engagement window.
TENGMX	Tank maximum engagement range.
TMEANH	The bias error in the horizontal axis for Tank fire.
TMEANV	The bias error in the vertical axis for Tank fire.
TRNG(i)	The firing range to assault wave TENG(i).
TSIGH	The standard deviation error in the horizontal axis for Tank fire.
TSIGV	The standard deviation error in the vertical axis for Tank fire.

TSURV	Total number of surviving LVA ashore at the current time.
TVEL	Tank projectile velocity.
TWTS(i)	The proportion of the total defensive force Tank strength to be allowed to engage wave TENG(i).
WB(i)	Aimed-fire attrition-rate coefficients for defensive force Tank and ATGM assets.
WID	Width of LVA.
WVINT(i)	Initial strength of assault wave i.
WVRNG	Firing range to assault wave i.

B. VARIABLE USED IN THE LAND COMBAT PHASE

ALPHA(i)	Initial attrition-rate coefficient for stochastic attrition option.
ANGH(i)	Orientation angle of the hill ellipse measured in degrees counter-clockwise from East to the major axis.
APOA(i,j)	The average proportion of the j^{th} attacker of Unit i allocated to fire on Unit i.
AVD	Average distance.
AVSP	Average speed of moving aggressor units.
BASE	Overall terrain elevation above sea level.
BREAK	Breakpoint distance between aggressor units and defensive units.
DISMAX	Maximum distance allowed between aggressor units before the leading unit is delayed.
DIST	The straight-line distance between two movement nodes input by the user.
DST	The distance in meters to be moved each time-step by aggressor units.
ECC(i)	The eccentricity defined as the ratio of major axis length to minor axis length.

FL(i)	Force level of Unit i.
FO(i)	Initial force level of Unit i.
IALT	Denotes whether the user desires alternate defensive positions or not: 0 - Yes, 1 - No.
IC	Counts number of time units a defender has been moving.
IDIR	Direction of j^{th} interval in i^{th} route.
II(i)	Interval index for Unit i.
IITIME	Current time.
IMAX	Maximum number of time intervals allowed.
IMOVE	Number of time units a defender is allowed for moving to an alternate position.
IPRDIR(i)	Primary direction of fire for defensive Unit i.
IRAN	Range.
IRTE	Denotes whether user wants to input routes or not: 0 - Program determined routes, 1 - User determined routes.
ISE	A switch variable set to 1 when the defensive force ATGM unit initiates its fire.
ISECWD(i)	Width of search sector for defensive Unit i.
ISPD	Input variable to denote user's desired speed for aggressor force movement: 1 - 9 MPH, 2 - 12 MPH, 3 - 15 MPH, 4 - 18 MPH.
IT	Current time period.
ITE	A switch variable set to 1 when the defensive force Tank unit initiates its fire.
ITEM	Input variable denoting number of time-steps allowed for aggressor unit move.

ITIME	Current time, in seconds, of battle.
ITRIT	Input variable denoting whether attrition will be stochastic or deterministic: 0 - Stochastic, 1 - Deterministic.
IUSTAT(i)	Current status of Unit i: 0 - Alive, not firing, 1 - Alive and firing, 2 - Killed, 3 - Moving.
LVAFR	Firing rate for LVA weapon system.
LATOB	Indicator variable for one- or two-way LOS calls: 0 - Do not compute LOS from Unit A to Unit B, 1 - Compute LOS from Unit A to Unit B.
LISTH(i)	List of hill numbers for each grid square.
LOA(i,j)	The number of the j^{th} target of Unit i.
LOST(i,j)	Denotes whether line-of-sight exists between Unit i and Unit j.
LOT(i,j)	The number of the j^{th} target of Unit i.
LST	Index number for the first hill listed for grid square (i,j) in LISTH(i).
MVTDIR(i)	Movement direction of Unit i.
N(i)	Number of nodes inputted by user for route i.
NA(i)	Number of aggressors of Unit i.
NBU	Number of defensive force units.
NCVELS	Number of forest ellipses in terrain.
NF(i)	Number of time units a Unit i is allowed to fire at the same location.
NHL(i,j)	Number of hills in each grid square (i,j).
NHILLS	Number of different hills to be modeled.
NHTOT	Total number of hills modeled on battlefield.

NLOSC(i,j)	Number of continuous time-steps that LOS does not exist between Unit i and Unit j.
NOD	Number of time intervals Unit i delayed in movement.
NOI(i)	Number of intervals in the i^{th} route.
NRU	Number of aggressor force units.
NT(i)	Number of targets of Unit i.
CFL(i)	Force level of Unit i during previous time-step.
P(i,j)	Probability of first round hit by Unit i in range band j.
PHH(i,j)	Probability of a hit following a hit by Unit i in range band j.
PHM(i,j)	Probability of a hit following a miss by Unit i in range band j.
PKH(i,j)	Probability of a kill given a hit by Unit i in range band j.
PM	The proportion of time a moving unit is searching for targets.
FOA(i,j)	The proportion of the j^{th} attacker of Unit i allocated to fire on Unit i.
FOL(i)	Percent of Unit i lost during the current time-step.
FTT(i)	Proportion of surviving firepower allocated to the i^{th} target if there are j targets available to be engaged.
RANGE	Current minimum distance between aggressors and defenders.
RKATTR	Vector containing the current attrition loss rates to be applied within the Euler integration routine.
RF	Detection rate reduction factor for a firing unit (in comparison to a non-firing unit).
RMINTK	Minimum effective range for an LVA mounted weapon system.

RMINTW	Minimum effective range for a TOW weapon system.
RMXTK	Maximum effective range for an LVA mounted weapon system.
RMXTW	Maximum effective range for a TOW weapon system.
ROF	Rate of fire.
ROT(i,j)	Range of the j^{th} target of Unit i.
SIZETK	Size of LVA weapon system.
SIZETW	Size of TOW weapon system.
SPRD(i)	Measure of hill size which is defined to be the distance in meters measured along the major axis from hill center to the contour line which is 50 meters down from the peak.
SUMBO	Total defensive force level.
SUMRO	Total aggressor force level.
SUPFAC	Suppression factor.
TA(k)	Time to acquire a target for k^{th} weapon system type ($k = 1, 2$).
TF1(k)	Time of flight to 1000m for k^{th} weapon system type ($k = 1, 2$).
TF2(k)	Time of flight to 2000m for k^{th} weapon system type ($k = 1, 2$).
TF3(k)	Time of flight to 3000m for k^{th} weapon system type ($k = 1, 2$).
TH(k)	Time to fire a round following a hit for weapon system type ($k = 1, 2$).
TI(k)	Time to fire first round after target has been acquired for weapon system type ($k = 1, 2$).
TM(k)	Time to fire round following a miss for weapon system type ($k = 1, 2$).
TMACI,TMACJ	Elevation of Unit i and Unit j in LOS model.
TOWFR	Firing rate for TOW weapon system.

TPOL(i)	Total percentage of lost since battle began for Unit i.
VISFR(i,j)	The fraction of Unit i as seen by Unit j.
VISFRA	Fraction of Unit A as seen by Unit B.
VISFRB	Fraction of Unit B as seen by Unit A.
X(i),Y(i)	Coordinates of Unit i.
XA(i),YA(i)	Coordinates of alternate position for defensive Unit i.
XC(i),YC(i)	Coordinates of center of hill i.
XIC(i,j)	Coordinates of the j^{th} interval endpoint of the route for Unit i.
YIC(i,j)	
XL,YL	Distance added to previous interval endpoint for vehicle to move DST during a time-step.
XLOC(i,j)	Coordinates of the j^{th} node inputted by the user for the route of Unit i.
YLOC(i,j)	

APPENDIX B

COMPUTER PROGRAM

for the

SMALL-UNIT AMPHIBIOUS OPERATION COMBAT MODEL

The small-unit amphibious operation combat model is a computerized model written in FORTRAN. It consists of a main program and 19 sub-routines. It was designed to serve as a reference to itself in order that the reader would not be forced to refer to various manuals outside of the program each time an explanation of the functioning of a particular aspect of the program was desired. A listing of the computer program follows.

```

C THIS PROGRAM IS A SMALL-UNIT AMPHIBIOUS OPERATION COMBAT MODEL
C UTILIZING LANCHESTER-TYPE EQUATIONS TO COMPUTE ATTRITION.
C IT CONSISTS OF TWO BASIC PHASES, THE FIRST BEING THE SHIP-TO-SHORE
C COMBAT PHASE, AND THE SECOND BEING THE LAND COMBAT PHASE.

SUBROUTINE ROUTE

*** SUBROUTINE ROUTE COMPUTES THE ROUTE OF EACH AGGRESSOR UNIT WHEN THE USER HAS SELECTED THE OPTION OF INPUTTING AGGRESSOR ROUTES. IT CALCULATES THE COORDINATES OF EACH INTERVAL ENOPCINT ALONG THE ROUTE, MAKING EACH INTERVAL LENGTH (DISTANCE MOVED DURING A 10 SECOND TIME STEP) THE SAME. THE INTERVAL LENGTH IS DETERMINED BY THE SPEED THE USER HAS SELECTED AND INPUTED FOR THE CURRENT BATTLE.

APPENDIX C

COMPLETE INPUT DATA SET

for the

SMALL-UNIT AMPHIBIOUS OPERATION COMBAT MODEL

The small-unit amphibious operation combat model consists of two phases of combat, ship-to-shore and land combat, and requires data input for each of these phases. The data set that follows is divided into two parts: the first part consists of all data used as input for the ship-to-shore phase of combat, and the second part consists of all data used as input for the land combat phase of combat. The input data set was designed to be self-documenting in that the input variable names or descriptive phrases are listed alongside the data being used as input to the model. The purpose of this documentation was to assist the user in associating the input data with their respective input variables. A complete input data set follows.

BLANK INPUT DATA SET

for the

SMALL-UNIT AMPHIBIOUS OPERATION COMBAT MODEL

The blank data set provided with the small-unit amphibious operation combat model was designed to assist the more familiar user of the model in the development of a new input data set to be analyzed by the model. It is patterned after the complete input data set listed in Appendix C providing input variable names or descriptive phrases to identify the locations of required input parameters. Underlining of the spaces following these descriptors is intended to serve as a guide for inputting values for the input variables in order that they will be compatible with the formatted read statements of the program. The blank input data set follows.

```

IPRINT = - 0 FOR EACH TIME STEP & 1 FOR END CF BATTLE.

APPENDIX E

EXECUTIVE PROGRAM

for the

SMALL-UNIT AMPHIBIOUS OPERATION COMBAT MODEL

The combat model presented in this thesis has been provided with an EXEC program which is designed to set up and execute all of the necessary CMS commands for the running of the model. The EXEC program will automatically BROWSE the output listing of the model (AMPHIB1 LISTING) allowing the user to review immediately the results of the battle.

A listing of the EXEC follows.

```
GLOBAL TXTLIB FORTMOD2 MOD2EEH IMSLSP NONIMSL CMSLIB
FILEDEF 05 DISK SEA DATA
FILEDEF 09 DISK LAND DATA
FILEDEF 06 DISK AMPHIB1 LISTING
LOAD AMPHIB (START)
BROWSE AMPHIB 1 LISTING
```

APPENDIX F

COMPUTER OUTPUT

for the

SMALL-UNIT AMPHIBIOUS OPERATION COMBAT MODEL

The computer output for the small-unit amphibious operation combat model was designed to be clear, concise, and identifiable to the user of the program. The combat model conducts two phases of combat: ship-to-shore and land combat. Therefore, the computer output was designed to report on each phase of combat. The computer output for each phase of combat begins with an initial information page which lists the input data provided by the user of the model. The initial information page serves as a record of the battle scenario analyzed by the model, as well as a check for the user to insure that the input data provided were read correctly by the model. In addition, a battle summary report is provided reporting on the status of both the aggressor and defender forces throughout both phases of combat. The computer output based upon the input data listed in Appendix C is as follows.

** INITIAL SHIP-TO-SHORE PHASE INFORMATION **

INITIAL FORCE STRENGTH
